She not only determines the chemical composition, but she looks after the temperature as well, and thereby gives a hint to the farmer of the proper temperature at which skim milk should be fed to the calf. She carefully excludes, from the vessel in which this milk is stored, every form of bacteria that can produce acidity or corruption, for milk fresh from the healthy cow, properly milked, is, until it reaches the air, absolutely free from all forms of bacteria, another hint to the farmer as to the sweetness and purity of the skim milk that should be fed to the calf.

Nature goes even further than this, and provides for the manufacture of milk in the udder practically as the calf needs it. It is now a well-established fact that the udder of the cow is not altogether a storage chamber for the milk secreted during the day or night, but that part of it is manufactured at the time of milking, whether by the calf or by the hand. Nature makes the process of milking an unalloyed pleasure both to cow and calf, the affection of the cow responding to the appetite of the calf. So careful, in fact, is nature in looking after the welfare of the youngster, that she provides that the chemical composition of the milk, the proportion of albuminoids, or flesh formers, ash or bone formers, carbohydrates or fuel, and sources of energy, shall not be greatly changed in any season or the life of one cow by any accidental or intentional change in the supply of her food. Were it otherwise, could the proportions of butter fat be greatly changed by accident or design, by scarcity or abundance of food, or change of pastures, the health and even the life of the calf would be in danger, and nature provides at all hazards for the safety of the life. Thus does nature in her way of growing calves, look with the utmost care after every vital point in the art and science of the business, namely, the quality of the milk, the quantity of it, the temperature, and the purity or freedom from germs.

And she succeeds. Where did human eye rest on a more perfect type of robust, vigorous life, filled with the pure joy of living, than on the three-months-old calf, as it follows its dam, either in the rich clover pastures, or the wild grasses of the plains or prairies. In the same proportion that we adopt nature's art and science will we achieve her success.

The exact chemical composition of nature's perfect ration for the calf has not yet, so far as we know, been determined with anything like absolute accuracy. The wild cow does not stand and deliver at the command of the scientist. She has a much higher regard for her calf, to her the handsomest in all the world, and the dearest, than she has for the chemist, no matter how great his reputation among men, nor the number of titles that have been bestowed upon him. These worthy gentlemen who are eagerly searching for nature's secrets, in order to lay them at the feet of the farmer, have not yet interrogated a sufficient number of the mothers of nature's calves to discover the mysterious and magical formula which nature uses in compounding her perfect ration. We know this, however, judging from the experience of farmers in growing calves from cows unsuited to dairy purposes, that nature's ideal ration contains a much smaller amount of butter fat than the milk of the cows kept for butter purposes, and a great deal less than the milk of the special purpose or dairy cow. "That cow gives poor milk, but she raises the best calves on the farm," is a remark farmers frequently make, and an experienced dairyman would never select the type of cow pointed out, for use in his herd. Whenever farmers select cows of this type for dairy purposes, they are obliged to discard a very large per cent of them for the sole reason that they lack in quantity as well as in quality of milk. We often hear farmers say, pointing to a calf that is not doing well, "I think the trouble with that calf is that its mother's milk does not agree with it, it is too rich;" meaning, of course, rich in butter fat. We know further that the Holstein, or special purpose cow giving the largest quantity of milk but carrying the lowest per cent of butter fat, will, if permitted to nurse her calf, produce a heavier calf at six months old than any other breed of cows in the United States. Still further, we know that while food rich in fat does not radically change the chemical composition of milk in the lifetime of a single cow, there is, nevertheless, a gradual change going on where dairying is practiced, and that breeds, gradually under the influence of food, environment and use, become noted for the richness of their milk in butter fat, and that with dairy practice cows gradually give richer and richer milk. (We have noticed also, that in dairies that supply milk to cities, the percentage of butter fat increases quickly when the law requiring inspection goes into effect.) It is, therefore, reasonable to suppose, that the wild or range cow gives a milk with a great deal less butter fat than the average farm cow, certainly not over, but probably a good deal under three per cent, and we would not likely be far from the truth if we were to guess that were half the butter fat taken from the quality of milk greatly desired in special-purpose cows, it would then not be far from the composition of the milk of the range cow, or nature's ideal ration. It is quite likely, however, that the per cent varies with the herbage on which even the range or wild cow is kept from generation to generation; less butter fat where the herbage is coarse and watery, and a large per cent where it is fine and more nutritious.

It is important to note carefully to what extent the demands which advancing civilization have made upon the cow interfere with nature's ideal ration. First, we demand that she shall give more milk, and second, that it shall be richer in butter fat. Instead of eight or ten quarts a day, we demand twenty; instead of milk with less than three per cent of butter fat, we demand six per cent, and will not be well satisfied with less than four per cent. We change the very form of the cow from a rectangular to a wedge, even if it lowers her vitality and destroys much of her value for beef production. This improved dairy blood is constantly infused in various ways, even into herds used for calf raising purposes only, so that some improvement in dairy qualities are carried back through the bulls even to the range, and much more to farm herds, with the result that many of the cows kept for calf raising only on the farms and in breeding herds give more milk than the farmer desires, or too rich for the real thrift of the calf, or perhaps both. On both farm and range, nature sooner or later makes the necessary correction so far as quantity is concerned, by decreasing the milk flow to correspond to the wants of the calf and arresting it at weaning time, while in thoroughbred herds she corrects the tendency to develop the extreme beef form at the expense of the normal dairy qualities which the welfare of the calf demands, by foreordaining that cows that can not support their calves shall be shy breeders. In other words, nature is constantly at work to promote the welfare of the calf by correcting the changes that civilization has made in her ideal ration and forming the milk of the cow to her ideal.

Modern practice, or shall we say advancing civilization, interferes with nature's ideal ration by removing for butter making purposes too much of the butter fat, even when gravity setting or the old-fashioned way of raising cream is still the custom. Under ordinary farm conditions, during the summer season when three-fourths of the calves are grown, from one-fourth to one-third of the cream is left in the milk where no separator is used, and if skim milk of this class could be fed sweet, warm and often, the ration would be out of balance, but not be so greatly out of balance as we might at first suppose. Unfortunately, in order to secure as much cream as possible, it is often allowed to stand until it is clabbered and then fed cold, thus violating three of nature's requirements, namely, a well-balanced ration, fed warm and sweet.

The advent of the separator creamery brought about a still wider departure. The separator, if properly constructed and well managed, leaves a mere trace of butter fat, often less than a tenth of one per cent, thus entirely robbing the natural ration of its fat and of its carbohydrates with the exception of milk sugar. As most creameries are conducted, this separator milk takes on a marked degree of acidity before it can reach the stomach of the calf and is generally fed at the temperature of the atmosphere, whatever that may be, and thus we have a very wide departure from the ration that nature intended for the calf. To increase this departure as far as possible, many farmers forget that most cows that are really reliable in the dairy, will furnish enough skim milk to grow two calves, and the calf not doing well on ten or twelve pints a day is encouraged to take twenty or thirty or even forty with the result that the more it takes the more pot-bellied and ill-shaped it becomes.

It is little wonder, therefore, that there is a violent prejudice among farmers who love good beef cattle, and among nearly all graziers and feeders, against the skim milk calf, against separator milk, and the entire creamery system. I had a letter last summer from a Nebraska farmer, inquiring as to the expediency of subscribing to the construction of a creamery in his neighborhood, and wished particularly to know if it was true, as reported in that community, that separator milk would take the skin off the calf's nose. It is little wonder, under the conditions above mentioned, that almost the entire breeding, grazing and feeding interests are more or less hostile to the extension of dairying, believing, as they do, that it tends to greatly impair the quality of the young stock of the country, and render them unprofitable for beef production. I am fully persuaded that this is an entire mistake, that calves inferior to nothing but the best—the fancy sorts—can be grown successfully on separator milk wherever their owners have the knowledge and skill to imitate closely nature's ideal ration. It can be done, it is being done on thousands of farms, and nowhere can it be done so cheaply as in the corn and grass states. That this ration must be duplicated exactly, I do not maintain nor believe. It is not within the range of human power to duplicate exactly the artistic work of nature when she has in view the perpetuation of the life of the species. We can, however, by substituting cheaper carbohydrates and fat for the dearer, which we remove from the ration, in the form of butter, come so near meeting nature's requirements that the slight lack of thrift in the calf can be compensated by the greatly increased profits growing out of the substitution. How to do this to the best advantage and greatest profit will be discussed in the following articles.—*Wallace's Farmer.*

Tuberculosis and Milk.

Much has been learned at the New Jersey experiment station in contravention of the wide-spread theory that the milk from tuberculous cows is the cause of much of the consumption among human beings. For some years the station officials have had under close observation several tuberculous cows, formerly part of the station's general herd. When the animals reacted under the delicate tuberculin test, they were not slaughtered, as is the general rule prescribed by the cattle commission of several states, but were segregated and studied. The information obtained is valuable and reassuring. An editorial correspondent of the *Rural New-Yorker* says that "the milk from these cows has been tested and analyzed, again and again, and thus far no germs have been found in it. So far as science can determine, these cows have produced clean and healthful milk." Editorially, the journal points out that although no germs have been found in the milk, "it is not safe to say that the milk has never contained any. The germs might be found in one milking and not in another, or in one single quar-

MEN AND WOMEN

Kidney trouble preys upon the mind, discourages and lessens ambition: beauty, vigor and cheerfulness soon disappear when the kidneys are out of order or diseased. For pleasing results use Dr. Kilmer's Swamp-Root, the great kidney remedy. At druggists. Sample bottle by mail free, also pamphlet. Address, Dr. Kilmer & Co., Binghamton, N. Y.

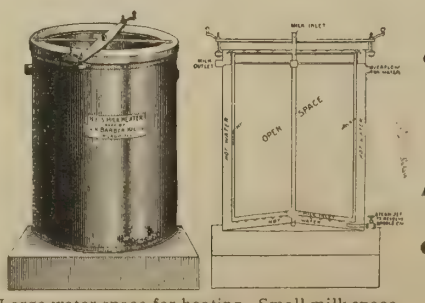
MARION HARLAND has written four new books.



THE FARMERS VOICE is the greatest Agricultural Weekly in the United States.

The Four Books and the Voice to Jan., 1900, for - 50c

The four volumes of Marion Harland are just out and are not on sale at the book stores. Vol. I on "Health Topics"—Vol. II, "Home Topics"—Vol. III, "Household Management"—Vol. IV, "Cooking Hints." Finely printed on heavy paper from new type and plates. Bound in heavy paper cover. The retail price of each volume is 25 cents, $1 for the set. The Farmers Voice is $1 per year. The books will be sent you free of cost, postage paid, and the Voice to Jan. 1, 1900, all for 50c. This phenominal offer will be open for a short time only. Address,

THE FARMERS VOICE, Chicago, Ills.

HILL'S MILK AND CREAM ...Pasteurizer

Large water space for heating. Small milk space. Will heat quickly and evenly throughout.

IS BUILT UPON CORRECT PRINCIPLES.

er of the udder. It is difficult to discover them, for the testing apparatus is not yet perfected. Still, it may be said that the germs in such milk are very scarce—if they exist at all." This conclusion solves the riddle as to how human consumption could be decreasing while tuberculous cows were on the increase. There are probably few dairy herds in which there are not one or more such cows, and, if the theory be accepted that the milk from these animals is always dangerous, the wonder would be not that there is so much consumption, but that there is so little.—*New York Press.*

The Horn Fly.

For the past few years this fly has been a great pest amongst the neat stock of our farms. This is particularly true on the dairy farms, as by the continued annoyance and pain caused by the fly the dairy cow shrinks materially in her milk flow.

The fly derives its name from its peculiar habit of resting at the base of the horns. While there it appears to do no particular harm, but confines its attacks to the backs and loins of the animal, and such other parts as cannot be readily reached by the tail or horns. This fly is about one-half the size of the house fly, but unlike the house fly does not breed in ordinary waste matter, but in the fresh droppings of the animals. The eggs are laid by the fly as soon as the manure is dropped, and if left undisturbed they will hatch in about 48 hours, when they immediately enter the ground and go through the second transformation. After remaining here about two weeks they emerge from the ground, a perfect fly ready for business. It will thus be seen that many generations will appear during the season.

Nearly everything that can be done to prevent their ravages must be of a preventive nature. They may be kept from breeding by scattering the voidings of the animals every two days or by sprinkling land plaster, lime, or dry earth upon them. They may be kept from the animals almost entirely by applying some oily preparation, or Pyrethrum powder. The liquid preparations are cheaper, and some of them are more effective. They may be applied to the sides and limbs of the animal to better advantage than the powder, another advantage in their favor. A gentleman in Knox county reports that he uses a mixture made of one part fish oil, one part tar oil, one part kerosene oil, with a very little carbolic acid. This, he says, is quite cheap and seems to be very effective.

It will be found advisable to apply this mixture with some implement that will put it on in a fine spray, as it will be quite as effective in this way; there will be a saving of material and the animals will not be unnecessarily covered with the oil.—*Maine State Board Bulletin for June.*

CONCERNING OUR ADVERTISERS.

JUST WEIGHT.

We have spoken frequently in these columns about the necessity of having all the farm work conducted after an approved method, so that the farmer can tell just where he is losing and where he is gaining, and regulate his mode of operations accordingly. Everything brought onto or taken from the farm should be weighed, measured or counted, and in this way only can the owner be certain that he is not going on year after year losing in some particular line. If he wishes to buy a scale that will be reliable, and every farmer should own a scale, we feel safe in calling his attention to the Osgood Scale Co., 91 Central Street, Binghamton, N. Y., whose advertisement appears in another column. The firm is thoroughly reliable, and we believe that our patrons will be well treated in dealing with them.

HE BELIEVES IN "SHOO-FLY."

The following letter from a prominent Texas merchant and stockman, explains itself:

HONEY GROVE, Texas, June 3, 1899.

SHOO-FLY MFG. CO, 1005 Fairmount Ave, Philadelphia, Pa.

Gentlemen:—Enclosed please find order for ten gallons Shoo-Fly. We have tried a number of remedies during the past three years, but nothing equals Shoo-Fly for the purpose of keeping flies, ticks, etc., from stock, and to heal up old sores. I use this on my herd of Jerseys and have the best results. Our firm also uses it on our dray and delivery horses with great success. While other teams are stamping and worrying themselves ours are not bothered in the least. We find it an excellent remedy for collar and saddle galls. If our horses and cows could talk we feel sure they would write you a vote of thanks. Kindly send the enclosed order at once. FRED T. HOCKADAY.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

CORRECTION.

Swollen testicle, page 401. Last line reads 7 grains of iodide of potassa. If a full grown bull, should read 70 grains of the iodide of potassium and less according to age and size.

STIFFNESS IN FRONT FEET. LAMINITIS.

We have a fine Jersey bull calf four months old, and of late have noticed quite a stiffness in front feet similar to laminitis. Lays down most of the time, but stays in fairly good condition Is laminitis inherited if the mother was foundered while pregnant?

Valley Mills, Ind. A. J. N.

ANSWER.

There is not any disease which is not, more or less, transmittible to the offspring, depending much upon the temperament of the mother. You give me a poor description to judge by. If the feet are sore between the hoofs, dress with compound tincture of myrrh and aloes daily. If possible, poultice them with carrots and flax seed boiled and put in as hot as can be borne.

OBSCURE SICKNESS.

I have a young cow that has been ailing about three weeks. She seems stiff all over, goes with her back humped, inclined to be down most of the time. She has lost some flesh, and fell off in her milk. She chews her cud as usual. E. CROPLEY.

Richmond, Ill.

ANSWER.

I don't like the symptoms at all. I believe my very best help to you will be, to recommend a personal examination by your state veterinarian, or by any truly qualified veterinarian surgeon. Your cow may be less alarming than I think she is, but a personal examination alone, can determine the true and correct condition.

CATARRH OF VAGINA.

Many thanks for answer in DAIRYMAN of June 16 about disease of cow. She was in calf, but aborted on 26th of May, 1½ month before time. She did not clean, and had to take out afterbirth. She got through all right, but now whites are appearing again as before. I intend to keep her from bull for four to five months, and try again the treatment you should be kind enough to give me to follow. Urine comes very often and little at a time, with some difficulty to expel it.

Guatemala. J. MONT.

ANSWER.

Catarrh of the womb, or vagina, is chiefly the result of retention of the placenta. Introduce a catheter, and draw off any fluid found there, and wash out with tepid water; add one ounce of Tilden's Bromo Chloralum to eight ounces of tepid water. After the washing try the catheter or tube. Inject the following: one dram of sulphate of zinc, dissolved in one pint of water to which add six ounces of pure glycerine. Repeat this injection daily, as long as needed.

MANGE.

We are told our cows have the mange, scabs all over them and a constant (almost) gnawing themselves. Have tried unsuccessfully sulphur and sweet oil, and a preparation from the drug store. R. E. K.

Greenville, Pa.

ANSWER.

Complete and thorough scrubbing, scalding, and burning of all clothing, etc., things which have come in contact with the disease. If this is not attended to, you will be constantly troubled with the disease, even the currycomb, brush, if any, and other things can, and do, spread the disease. Pyroligneous acid, 16 ounces, oil of tar, one ounce, fish oil, 25 ounces. Thoroughly mix and work into the bottom of the scabs twice a day for a while, feed well, give plenty of roots, any kind they will eat.

BLOODY MILK.

I have a young cow, two years old, first calf, that gives bloody milk out of two teats, and has been so for two weeks or more. Her health seems to be good, and is in good condition; is running out in pasture. J. C. C.

Rhinelander, Wis.

ANSWER.

Immediate full dose of physic and repeat in six days, and if needed repeat. Each morning give two teaspoonfuls of nitre for ten days or longer, if needed. Don't forget the physic, it is of paramount importance to your cow's present condition, and cures alone eighty per cent of similar cases. Sometimes change of food is very useful in stopping the discoloration of the milk. If it is not blood, it is caused by acrid plants found in the pasture, also in the mill feed and bran.

TO CHANGE TIME OF COMING IN—STIFFNESS—CASTOR OIL FOR WARTS.

My cows come fresh in the spring, and I wish them to freshen in the fall. Which had I better do, keep the bull away from them until the proper time, or give powders to hurry them up after freshening each time until they come right?

Have a cow that goes about very slowly, acts as if she was sore all over and afraid to move. Eats well and seems all right otherwise, but is getting very thin. What can be her trouble and treatment?

Have tried castor oil for warts on teat, for two months, but see no effect. E. M. L.

Lockeford, Cal.

ANSWER.

I object to interfering with the natural laws of nature. This is always wrong. Let the cows take their proper, natural course.

It is hard for me to say what the cause may be for the stiffness you name, as it may be result of many causes—colds, injuries of any kind, etc. Give a moderate physic once or twice, six days apart.

Try nitric acid, and butter of antimony, alternately; touch only the warts.

TUMOR ON THIGH.

I have a fine Jersey cow that has a growth on the left thigh. It is nearly as large as a person's head, and equally as hard to the touch. Last April I found a spot in the lower part that seemed to be softer. I opened it and it discharged a watery substance, that reduced the size quite a little. At present it is as large as it was before I made the opening. She is not lame.

Valley Falls, N. Y. C. M. G.

ANSWER.

You did wrong to open the tumor. If it had been ripe for opening it would have been proper. Such opening always does harm. There is nothing to do now that I know of, but to try to bring the tumor to a head and then have some one capable, open the tumor to the bottom and keep it running. This is the only way to cure it. Blistering or poulticing, or both, may bring the tumor to a head. But after the opening the tumor has become solidified, that is, it is a mass of gristly substance.

POOR DEVELOPMENT OF UDDER.

I have a nice heifer that I would like to keep for a milch cow, but her front udder is not developed equal to the back and two of her teats, front and back, are so close together (and the skin grows down to within an inch of the end of the teats) that I can not milk her except by stripping between the thumb and finger.

Is there any method to develop the front udder to equal proportion with the hind? Would it be safe to cut the skin of the udder between the two teats, and would it injure the udder proper, aside from the skin, if the udder was slightly cut, the cutting to be done just as the heifer begins to show signs of udder filling before calving?

Both hind teats have a tendency to stick forward and I think could be remedied if the front udder could be well developed, or would it be safe to cut the udder proper inside of the skin and allow the teats to separate in that way? AN OLD SUBSCRIBER.

Agassiz, B. C.

ANSWER.

Thousands, many of them of good cows otherwise, fail in development of the front part of the udder.

No. Such an act is quite out of the question. Sell her. I would not own such a cow for a good milker. Cutting, etc., is simply preposterous and quite against common reasoning.

HARD UDDER.

Have a cow that came in with her second calf on June 30. Was unable to dry her up. Udder seems hard, but not lumpy, hot or painful. Gave her your physic and have rubbed udder with lard and alcohol twice a day, sponging off with hot water just before milking, feeding on pasture only. Milk twelve hours apart but quantity of milk yielded varies. V. E. C.

St. Paul Park, Minn.

I recommend alcohol and lard for attenuated, shrunken udders, but never for garget. Such application would add fuel to the fire. Repeat, and repeat the physic if needed. Rub the udder with strong tincture of camphor six parts and common turpentine two, only, parts; rub tolerably hard, the first day twice, then only once a day for two to four days; after the physic is over give her 60 grains of iodide potassa each day for 10 to 30 days. This will not spoil the milk for domestic uses. Use daily massage, rubbing kneading etc.

Horse Owners! Use GOMBAULT'S Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING. *Impossible to produce scar or blemish.*

Short Course In Agriculture at Madison, Wis., To Be Largely Attended the Coming Winter.

ED. HOARD'S DAIRYMAN:—The coming term of the Short Course in Agriculture, which begins December 5th, and closes March 8th, promises to surpass all previous terms in attendance and character of the work outlined.

One hundred and fifty young men have already declared their intentions of taking the course and have been duly enrolled as students. Applications will be received at the office until the opening of the term. All students must register in advance, and it is advisable this year to register early, as the college may be obliged to limit the number, and students will be accepted in the order of their application.

The character of the work is of such a practical nature and so beneficial to those who attend that the short course in agriculture has become one of the most popular courses of the University.

The new illustrated circular describing the course is now ready for distribution and can be obtained by sending request to

Madison, Wis. R. A. MOORE.

Does Education Pay?

[Press Bulletin.]

The college dairy finds that it does. Before the first of April, '99, the herdsman at the Kansas Agricultural College was a man with no special training along agricultural lines. He was a good man to do what he was told and to draw his salary, but there his interest ended. When asked how the recent snow storm or change of feed affected the milk yield of his cows, he didn't know, although he had weighed and recorded each milking. During this time the college was feeding four head of calves on skim milk, and this herdsman made them gain at the rate of thirty-three pounds per month per head, or 1.12 pounds per day.

On the first of April, a graduate of the college and a special student in dairying took up the work of herdsman. He is a man that is constantly on the alert for new developments. When milking a fresh cow he can scarcely wait until the milk is weighed in order to see if there is a gain or a loss from previous milkings. When the calves are weighed he wants to know immediately how much they gained. With the same feeds at his command he made the four calves, mentioned above, gain an average of fifty-three pounds per head per month, or one and eight-tenths pounds per day, an increase of sixty per cent. This was done by carefully watching the calves; the moment one of them began to scour, he saw it, reduced the supply of milk, gave a little castor oil, and in various other ways sought to bring it back to normal condition. This was accomplished in about twenty-four hours, when the calf would keep on gaining at the rate of a pound and a half or two pounds per day.

Yet there are farmers who say that education don't pay, and that book learning is a farce. There is no profession in the universe that allows a greater display of intellect than farming, and nowhere is it needed more in order to increase the profits. The farmer is called upon to solve questions in soil physics, in chemistry, botany, entomology, bacteriology, veterinary science, mechanics—and in fact, can call into play a knowledge of all the sciences and arts. To do this he must be educated. This education not only makes him a better farmer, but makes his work a pleasure. No one who has not experienced it can appreciate the satisfaction that comes from seeing a plant, an insect, a bird, or an animal of any kind, and to be able to name it andtell something of its life history.

Kansas Experiment Station.

More Testimony Against the Hydraulic Separator.

Agents for the hydraulic separator recently canvassed the country about Cherokee, Ia., for the sale of this device for separating cream from the milk. Realizing that few farmers have the facilities or apparatus with which to test their milk and thus the effectiveness of the new separator, Mr. S. J. Fairfield wrote to Prof. Curtiss at the state agricultural college for an opinion on the merits of the device. In reply he received the following letter from the director of the Dairy School at the agricultural college:

AMES, Ia., June 14, 1899.

Mr. S. J. Fairfield, Cherokee, Ia.—Dear Sir—In answer to your letter would say that I consider the hydraulic separator to be one of the biggest frauds that have been placed before the dairymen for some time.

In our experiment here with it, we found it left in the milk nearly one per cent of fat, and in some cases more, or in other words it left one pound of butter to every one-hundred pounds of milk. Experiments were conducted at Cornell, also at the station in Vermont, where same results were obtained.

We have had as good results when using just a common milk can and pouring cold water in with the milk, thus causing a separation of the fat.

This skim milk is not as good for the calves as ordinary skim milk, as they have to drink twice as much as of ordinary skim milk to obtain the same amount of solids.

G. L. MCKAY.

—*Chicago Produce.*

HOARD'S DARYMAN will not even inferentially endorse these so-called separators, by allowing them to be advertised in its columns. Certain manufacturers cannot seem to understand why we should deliberately decline to receive their money for that purpose, but old time readers of the paper well know that the DAIRYMAN is published in the interests of the dairyman and never knowingly leads him astray.

Sub-Earth Duct.

Its Value in Lowering the Temperature of Curing Rooms.

The following letter addressed by instructor Morrison to Mr. George Hately, secretary of the Cheese and Butter Association of Western Ontario, furnishes additional evidence as to the value of the sub-earth duct as an aid in controlling the temperature of the curing room in a cheese factory:

"In reply to your request for information regarding sub-earth ducts which have been recently added to the curing rooms in my district, I submit the following report:

Caistorville—The sub-earth duct is completed and in operation. The duct is eight feet deep and extends 118 feet under ground. It is made of three rows of five inch tile, two rows of six inch tile, and one row of eight-inch tile, all laid close together with the eight-inch tile in the middle; over the tile there is a covering of rye straw.

In digging the trench for the tile a spring was found near the factory. The water from the spring runs in the bottom of the trench for its entire length, which possibly somewhat increases the moisture in the curing room. The in-take pipe is built of galvanized iron, fifteen inches in diameter and thirty feet in height, with cowl on top The outlet from the curing room is simply a hole in the ceiling on the opposite side to that at which the duct enters.

On the day on which I visited Caistorville the temperature on the outside in the shade was 85 degrees. Inside the curing-room a strong breeze was coming in from the duct at a temperature of 60 degrees. The temperature of the curing-room did not exceed during the day 69 degrees. The curing room at this factory is very poor. I am of the opinion that with a reasonably good curing-room the temperature can easily be held at 65 degrees. The moisture in the curing-room was from 80 to 82. There was no mould on the cheese."

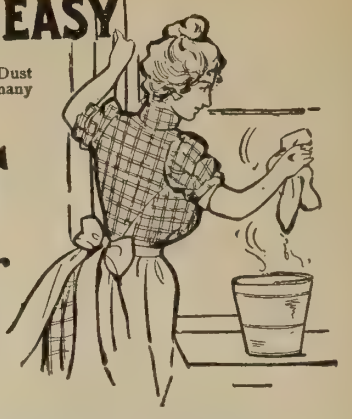
As we pointed out some time ago, a distinctly forward movement has been inaugurated in the Province of Quebec in regard to curing rooms and curing cheese, and the dairymen of this province will have to be on the alert if they wish to maintain the position they now hold as producers of the finest quality of Canadian cheese. The sub-earth ducts furnish a very simple and yet effective means of very largely controlling the temperature of curing rooms, as Mr. Morrison's letter very clearly shows, and every cheese factory in the country should have one built. Their construction is not difficult, and a suitable duct could be put into every curing room at comparatively little cost.

In fact, if there were no other means of doing so, a few of the patrons, under the direction and with the assistance of the maker, could put one in in a very short time, and its cost would be more than paid for, in one season, by the improved quality of the cheese, and by preventing any loss in weight, due to the excessive heat of July and August.

Of course a sub-earth duct will not make up for a poorly ventilated, and a poorly constructed curing room. But even the temperature of a poorly constructed curing room can be very much improved and controlled, if it has one of these ducts in connection with it. We would advise every factory to no longer delay this matter. We are just entering upon the two most trying months of the year for curing cheese, and if a factory has not already done so, there should be no further delay in getting in a sub-earth duct. Curing the cheese properly is of the utmost importance in enabling Canadian cheese to retain the position it now holds in the British markets.—*Farming.*

See in this connection, Mr. Aderhold's report on the duct put in the Fassbinder factory at Bungert, in Wisconsin.

Milk Without Dirt.



Yesterday, some sixty visitors were entertained at Clover Leaf farm, and under the explanation of the proprietor, H. B. Gurler, and his able assistants, the process of preparing the well known certified milk was made plain. The occasion of the gala day at the farm was the entertainment of twenty-five graduate nurses and physicians from Chicago, and the party swelled by the presence of several physicians from the vicinity, and interested people from De Kalb. Mr. Gurler accompanied the trained nurses and physicians from Chicago on the afternoon train and they were met at the depot by carriages, and conducted to the farm four miles southwest. Arriving there they proceeded to the barn where the 130 cows were being milked by men in clean, white uniforms, the milk weighed, filtered through sterilized cotton batting and through a strainer, and carried to the house. The model stable with its white walls, cement floors and iron stanchions are all conducive to cleanliness, it being Mr. Gurler's underlying idea to keep the milk in the perfectly clean condition in which it comes from the udder. Milking time in the afternoon begins at three o'clock each day.

At the house, the most perfect of dairy arrangements are in practice. The milk, as it comes from the barn, is strained into a vat, and through a faucet in the bottom of it is poured over a ladder like machine filled with ice cold water and cooled. From here it enters the separator, and after the cream is separated from the milk it is mixed again according to perfect proportions, four per cent cream to ninety-six per cent milk. It is immediately bottled, corked with a dated cork and sealed with the Clover Leaf seal, is packed in wooden cases filled with ice and in the morning shipped to the Chicago market or sent to supply the home trade. One thousand seven hundred bottles are sent out daily. The whole process indicated such perfect cleanliness that the nurses and physicians in search of a milk food for invalids were of the opinion that no better could be found than on Clover Leaf farm. As a further entertainment Mr. Gurler treated them to a delicious supper on Clover Leaf farm, and escorted them on a sight seeing tour about the town before they took the evening train for home.—*DeKalb, Ill. Chronicle.*

MAKES CLEANING EASY

"Many hands make light work," and so does Gold Dust Washing Powder. If you are not in a position to employ "many hands" in your housework, you will be both pleased and astonished to see how much you can do with one pair of willing hands by using

GOLD DUST Washing Powder

With it you can do your cleaning easier, quicker, cheaper and better than with soap or any other cleanser. Try it and be convinced.

For greatest economy buy our large package.

A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

WE make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue, which fully illustrates and describes this wagon and 10 other styles.

THE O. ARMLEDER CO., Cincinnati, Ohio.

Be Fair with Your Fields *and they will be fair with you..... Listen a moment.*

Every time you take a crop off a field you relieve it of just so much fertility. You should do something to restore that fertility. Barn yard manure is the best fertility restorative known if properly handled and properly applied. Even a small amount can be made to go a long way and accomplish great good if finely and evenly spread. This cannot be successfully done by hand—it is work for a perfected machine. The only machine known which accomplishes this is

The KEMP MANURE SPREADER.

It will Double and Treble the Value of the Manure Heap.

It spreads all kinds of **fine and coarse manure evenly;** it makes no "skips;" does not dump a great load in one spot, but covers the entire ground evenly. Tears up coarse and lumpy manure and makes it fine. Better than anybody can do it by hand. **Spreads lime, wood ashes, salt, etc.,** equally well. With the drill attachment **it puts the manure direct into the open drill.** Made in three convenient sizes. Ask the opinion of anybody that uses one. **Write for illustrated catalogue.**

Kemp & Burpee Mfg. Co., Box 46, Syracuse, N. Y.

THE NEW BOOK

Feeds and Feeding

By Prof. W. A. HENRY,

Wisconsin Experiment Station.

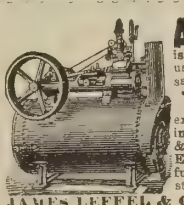
This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.



This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

Largest manufacturers of Steel Wagon Wheels and Handy Truck Wagons in America. Guaranteed superior to any other make

SMALLEY MFG. COMPANY, Sole Makers, MANITOWOC, WIS.

MAKE ONLY SWEET ENSILAGE

Ever since the ensilage system has been introduced in this country it has been the ambition and effort of siloists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste.

The best way to Shred Ensilage is with the

St. Albans Ensilage and Fodder Shredder.

It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail free a pamphlet on the subject.

LIKE A SNOW FLAKE

Did you ever watch a snowflake dissolve in your hand? Then you know exactly the process by which "the salt that's all salt" permeates the butter so thoroughly, so easily. This soft, flaky nature of

DIAMOND CRYSTAL SALT

is one of its best recommendations—but not the most important. Its purity is its strongest point. You can rely on it absolutely, and all the time. It's the salt butter makers use who want to be sure of success. Book sent free.

DIAMOND CRYSTAL SALT CO., St. Clair, Michigan.

THE DIAMOND CREAMERIES

— AND —

The SHARPLES TUBULAR Separators.

The Facts Are These: Simpson, McIntyre & Co., are owners of the Diamond Creameries. They are the largest handlers of high class butter in America. They operate over half a hundred factories in Iowa and New York. The separators they have in use were made years ago, and they will replace them with the best that are now to be had. With this in view, they have been testing for some months at their principal Massena, N. Y., factory, the different leading separators on the market.

They are conservative business people who have little to say but know how to make money.

Their letter is just a plain business one and not intended especially for a testimonial, so will bear weigh: accordingly.

BOSTON, MASS., April 12, 1899.

P. M. SHARPLES, Esq.,
West Chester, Pa.

Dear Sir:—We have concluded to place an order for your No. 25 Tubular machine, which we consider the most practical separator in use at the present time. It is quite possible that we may decide to order some of the No. 40 Tubulars for our large points, but after a trial of the No. 25, for several months, by the side of some others of leading makes, we have decided in favor of the Tubular, and also think for all purposes the No. 25 machine will come the nearest to meeting our requirements. It is our intention to make the changes as fast as our men become educated to the machine sufficiently to run them in a proper manner.

Trusting you will lose no time in filling our first order, we are, Yours truly,
Dic. G. W. S. SIMPSON, McINTYRE & CO.

If such firms as this, after extended and exhaustive tests find the Sharples Tubular Separators the best, they are safe people to follow.

Small Diameter, Medium Speed,
High Revolutions,
Give Greatest Effectiveness.
Clean, Rapid Skimmers.
Fine, Smooth Cream.

Handles hot milk or cold milk, fresh milk or stale milk.

Send for Catalogue No. 46.

The Sharples Co.,
Canal and Washington Sts.,
CHICAGO, ILL.

West Chester, Pa.,
U. S. A.

BRANCHES—Toledo, Ohio. Omaha, Neb.
Dubuque, Ia. San Francisco, Cal.
D. DERBYSHIRE & Co., Brockville, Ont.

ALDERNEY BUTTER COLOR

Gives **Natural June Tint.** Butter colored with it will retain its color when put in cold storage. Try it and be convinced.

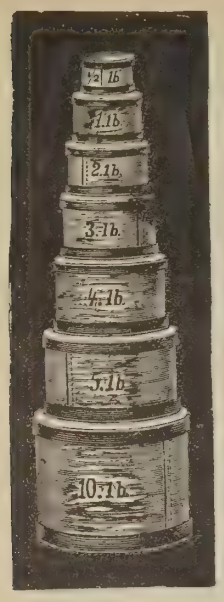
Manufactured by THE HELLER & MERZ CO., Office, 55 Maiden Lane, N. Y.

BRANCHES:—Chicago, 14 No. Clark St.; Boston, 98 Commercial St.;
Philadelphia, 109 South 2nd St.

THE RUSSIAN BABCOCK TESTER....

is preeminently the machine for the man who wants to read small quantities correctly.

RAPID WORK



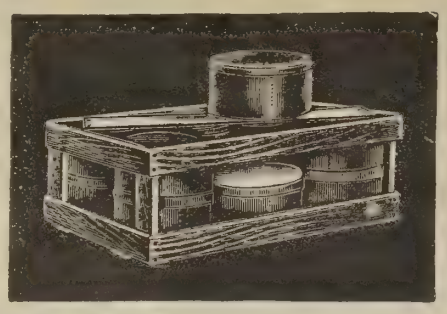
is easily accomplished, for the machine is not stopped when the bottles are filled with hot water. It is a

High Grade Tester,

driven by steam. Ball bearing, automatic speed gauge, and with little care will last a life time.

We are prepared to repair all cream separators, and have the most skilled men for this work. Send for Catalogue, No. 51.

ELGIN MANUFACTURING CO., ELGIN, ILL.



Butter Boxes

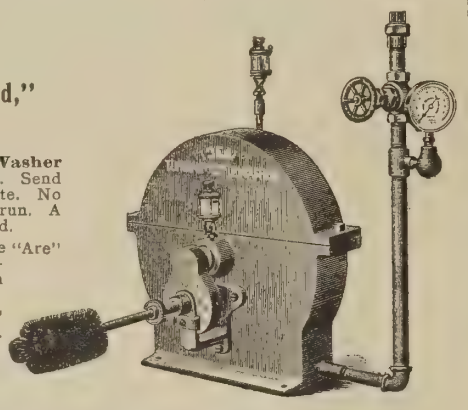
We carry the Largest Stock and greatest variety of Butter Packages of any house in the country.

Our . . .

ROUND SPRUCE BOXES...

And BRADLEY BOXES are two very popular styles. The Round Spruce are made in the 5 pound size only. The Bradleys can be had from ½ pound up to 10 pounds.

Whatever the demands of your particular trade, we can supply you with the best package for your purposes



Some New Things are "No Good," some "Are."

The New IDEAL Steam Turbine Bottle Washer belongs emphatically to the "Are" class. Send for cuts of tanks and Turbine, complete. No belts, pulleys, or shafting, nor engine to run. A small boiler or steamer only is required.

The POTTS PASTEURIZER belongs to the "Are" class too. It is the only *perfect* Pasteurizer made. Send for circulars of it, which tell you why.

If you are in need of anything "*whatever*" in the Dairy or Milk Dealers' line, write us. *We are sure* to have it.

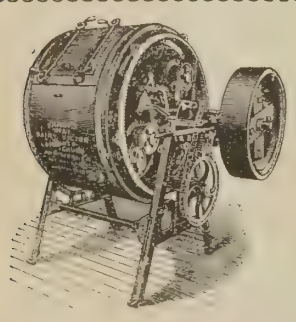
Send for our Milk Dealers' Price Current.

Alpha De Laval Separators, Ideal Turbine Testers, Disbrow Churns, Elgin Style White Ash Tubs, Ideal Corrosive Sublimate Tablets, Parchment Paper, Australian Boxes, Refrigerating Machinery, Boilers and Engines, American and Lusted Printers, Genesee Salt, Potts Pasteurizer, Etc., Etc.

Creamery Package Mfg. Co.,

BRANCH HOUSES:— **1, 3 and 5 W. Washington St.,**

Minneapolis, Minn. Kansas City, Mo.
Waterloo, Iowa. Omaha, Neb.



CHICAGO, ILL.

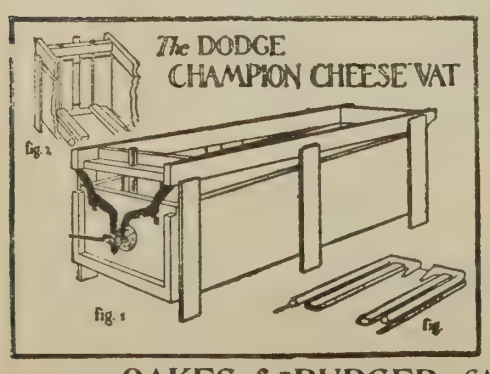
We are General Agents for Hansen's and W. & R. Butter Color.

Star Milk Cooler Co., ARCHITECTS, CONTRACTORS, and SANITARY DAIRY ENGINEERS.

HIGH GRADE WORK ONLY. **Haddonfield, N. J.**

Send for Catalogue of Sanitary Dairy Apparatus.

THE DAIRY "VICTOR" Churn.



This Combined Churn and Butter Worker is proving itself to be precisely what the farmers and dairymen have been seeking after. It's work is as complete as the work of the "Factory" Victor Churn, which is rapidly supplanting every other Combined Churn and Butter Worker.

IT IS THE ONLY SUCCESSFUL DAIRY COMBINED CHURN AND BUTTER WORKER ON THE MARKET.

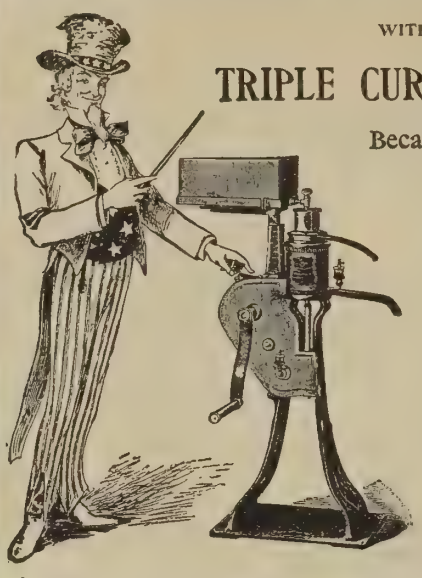
It is easy to handle, easy to clean, perfect in its work, durable and reliable. It charms every farmer and dairyman who sees it work. Manufactured by . . .

F. B. FARGO & CO., Lake Mills, Wis.

THE DODGE TILTER ...FOR CHEESE VATS...

An important improvement Tilts vat tin only, thereby avoiding racking the wood vat when drawing off the whey. Vat tin so supported that no possible injury can come to it. Requires but slight effort to throw the lever. Can be adjusted to any style of vat.

WRITE FOR PRICES.



OAKES & BURGER, CATTARAUGUS, N. Y.

Uncle Sam Points with Pleasure to

The Improved U. S. Separator

WITH ITS

TRIPLE CURRENT BOWL

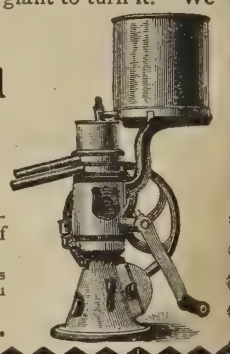
Because it

Skims the Cleanest,
Operates the Easiest,
Is the Easiest Cleaned,
Is the Most Durable,
And in other important points Excels all other Separators.

It does equally good work in the Dairy or Creamery as testified to by users the country over.

If interested, send for our large illustrated catalogues giving full particulars and containing hundreds of testimonials from users.

Remember we furnish everything necessary for a first-class Dairy or Creamery.

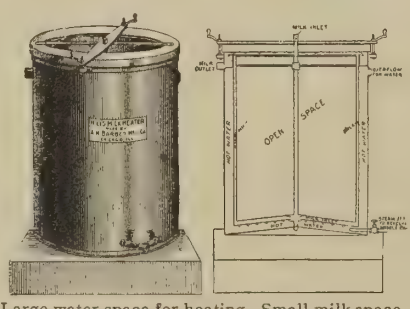


VERMONT FARM MACHINE CO., Bellows Falls, Vt.

A Hand Separator

to be profitable must not only extract every particle of butter-fat from the milk, but must run so easily that it does not require the strength of a giant to turn it. We guarantee the

Empire Cream Separators



to run 50 per cent. easier than others of equal capacity. Their record for clean skimming is unequalled. We have the most complete line of hand separators in America; also power machines.

We have not space here to tell you why the **Empire** machines excel all others, but it's all in our catalogue. Send your address if you have one cow or one thousand.

U. S. BUTTER EXTRACTOR CO., Newark, N. J.

HILL'S MILK AND CREAM ...Pasteurizer

Large water space for heating. Small milk space. Will heat quickly and evenly throughout.

IS BUILT UPON CORRECT PRINCIPLES.

Try it and you will be convinced. Made by

A. H. Barber Mfg. Co.,
CHICAGO, ILL.

Reading notices, 50 cents per line (nonpariel measure) each insertion

A smooth agent has been operating in the neighborhood of Bloomington, Ill., selling a prescription for $5, for making eight pounds of butter from a gallon of skim milk. A number of sales were made. A gallon of skim milk weighs only eight pounds and 12 ounces, water and all. Is there any swindle that will not find takers among a class of people who cannot afford to read and know better?

New Jersey is the home of other dangerous things besides trusts. Out of seven hundred and fifty samples of food and drugs analyzed by the state chemist, two hundred and eight of them were found to be adulterated.

This is merely a drop in the ocean of mixed, preserved, colored, doped and doctored foods, that we are compelled to buy for want of a better article. But the protest is being heard in the high places, and the probability is, that the adulterator will soon be forced to stop this profitable poisoning, and sell pure food at a reasonable price. In the meantime he is working and pushing his objectionable methods for all the money there is in it.

Concerning the illustrations on this page, there is little or nothing new to be said. The high grade heifer, Browny No. 2, was sired by the bull Gifford, whose picture we printed in 1897. Commenting on it at that time, we said:

"Dividing this picture into three parts, we find the rear third to possess a typical dairy form, and if upon examination, large and well formed rudimentary teats are found, we should be disposed to award this section nearly or quite the maximum of 50 points. We are not so well pleased with the middle third, for the reason that it is lacking somewhat in depth, which indicates a possibility that his progeny may be deficient in digestive capacity. The front third is better, as it shows a high, thin shoulder, (the very opposite of the typical beef form), deep, roomy chest, short legs, and a neck not particularly objectionable, although the falling away behind the horns detracts somewhat from the general symmetry of his appearance—a defect, if it is one, likely to disappear with greater age."

Mr. Long writes us concerning the heifer, that she was 21 months old at time of calving, that the photograph from which the engraving was made was taken four weeks later, and that when the calf was seven weeks old the heifer was giving 22 pounds of milk per day, on a daily ration of 4 pounds wheat bran, 3 pounds corn chop and 1½ pounds cotton seed meal, 6 pounds prairie hay and what green feed she can find in the cotton fields.

How does the picture of the heifer and this record correspond with the comments made on her sire two years ago? It would be pretty near a "fool's errand" to attempt to find a better rear third than this heifer shows and probably inherited from her sire. She has the thin incurving thigh and the arching flank, which are nature's provisions for a capacious udder, and without which she would be working at a disadvantage; she has the rising pelvic arch, which is the proper structural form for supporting the extra burdens which the modern dairy cow must daily carry around—a striking exemplification of nature's generous care in adapting form to function; she has a well shaped udder, especially in its front development, and four widely separated and squarely placed teats.

The defect noted in the middle third of the sire seems also to have reappeared in the daughter, although it is but fair to say that the appearance of these parts four weeks after calving, is possibly misleading. That the heifer is producing as much milk and of as good quality as ought to be expected of any heifer of her age and breeding, is not a full or satisfactory answer to the objection here suggested. With a better middle piece to supply the milk making organs in the rear third, she might do much better, both in total yield and, what is at least equally important, in reduced cost of production. It is somewhat like running a large engine with a small boiler. With such a combination it is impossible to get the maximum of service or the minimum of cost.

The accompanying illustration of the registered Jersey, tells its own story. We have but little information as to her breeding and performance. She shows many excellent "points"—enough to justify the estimate of her owner, that during her first milking period, which lasted 15 months, she yielded nearly or quite 500 pounds of butter, which he sold at 25 cents per pound. Her udder is not as symmetrical as that of Browny 2d, which detracts somewhat from her merit as a show animal and for raising the highest priced stock, but we have frequently observed that unsymmetrical udders make up in labor what they lack in looks.

GRADE JERSEY HEIFER, BROWNY 2nd.

Property of Geo. M. Long, Delta, La.

The Best Known Hogs.

The leading breeds of hogs grown in the United States are the Berkshires, the Poland-China, the Duroc-Jerseys, the Chester-Whites, the Essex, the small Yorkshires, the Suffolks and the Victorias. The Berkshires are of English origin and were first brought to the United States in 1830. They are famous for quick growth. They may be put in good condition for killing at the age of five months and even less, but they go on gaining in weight until they are two years old. They are active pasturers and respond quickly to fattening food. The sows are very prolific and good mothers. The Berkshires lose less in dressing than do most other breeds. At the same time their dressed weight includes a slightly greater proportion of fat than other breeds show.

The Poland-Chinas are a composite stock of recent origin, developed in the great corn region of this country. They originated in Ohio. The stocks that were crossed to produce them are the Big Chinas, the Irish Grazier, the Poland and the Byfield. The name Poland-China was given in 1840 to a large and coarse black and white hog which required two years to mature, growing to an enormous size, and reaching, in many cases, a weight of 600 to 800 pounds. A cross of these giants with Berkshires gave a smaller, finer, smoother, and earlier maturing animal, closely resembling the Berkshire in form and color, but retaining a larger degree of its power of continuous growth, up to the age of three or four years, and dressing out a carcass which is nearly all merchantable meat. They are not so good grazers as the Berkshires, not so well able to care for themselves when turned into the woods, but they have a quiet disposition, are controlled easily, grow rapidly and fatten quickly. They bear close confinement better than the Berkshires, but are not quite so prolific, although some Poland-China strains are extremely prolific.

The Duroc-Jerseys are large, long-bodied, red hogs, which are good feeders, easily fattened, and grow very rapidly when well fed. They have come into prominence during the last fifteen years, being descendants of the Jersey Red and the Duroc breeds, which have long been popular in Pennsylvania, New Jersey and New York. The blending of the two has produced an animal which is easily kept or fattened, is small-boned, vigorous and prolific. Being very long-bodied, the proportion of side meat to ham and shoulders is larger than in most other breeds, but many consider this an advantage, and the breed is growing in favor wherever it has been introduced.

The Chester-Whites are the most popular of the white breeds. They take their name from Chester county, Pa., where they originated by crossing the native white hogs with some large white hogs brought from England about 1825. Selection from the offspring of those crosses has made a great improvement on the form of the earlier animals, and has developed a hog quite similar to the Poland-China in shape, and differing from that breed but little excepting in color. Where any white hog is to be grown this is the best for general purposes.

The Essex is a small black hog of English origin. It is valued more for its quiet disposition, its rapid growth when young, and early maturity, than for its size or its ability to produce a large amount of meat. Where there is a local demand for well-matured hogs of small or medium size, or for pigs of which one or two are to be kept in a small pen and fed principally on slops from the house and the refuse from the garden, the Essex is a valuable animal, but is not generally popular for ordinary farm purposes, or for making large amounts of pork under ordinary conditions.

There are many other breeds of more or less prominence and value for one or another purpose, but in the south about 90 per cent of the pure bred hogs are Berkshires or Poland-Chinas, while in the north, especially in the great corn states, the Poland-Chinas predominate.

To show that there is practically very little difference in the meat-producing capacities of different breeds, Professor Henry, of the Wisconsin Experiment Station, reports a test extending through 224 days with a Berkshire boar and four sows, together with a similar lot of Poland-Chinas. The total gains and the amount of feed required for each 100 pounds of gain were as follows:

	Berkshires.	*Poland-China.*
	lbs.	lbs.
Total gain of lot.....	1,167	1,168
Feed for 100 lbs. gain..	512	524

—*New York Farmer.*

Embalmed Milk in New Jersey.

The Newark, New Jersey, Board of Health has discovered that much "embalmed" milk is sold in that city; milk dosed with formaldehyde to keep it from souring; milk particularly dangerous to infants, for the formaldehyde upsets infantile digestive organs. An immense quantity of New Jersey milk is sent to New York. Another thing, formaldehyde is made from wood alcohol and chemically stands between methyl alcohol and formic acid. If the formaldehyde is not properly made, wood alcohol remains in it. One part of formaldehyde in 50,000 of milk will keep the milk sweet for two days in summer. But Herbert B. Baldwin, chemist to the Newark Board of Health, has found cases where the dairyman who sold the milk, put formaldehyde in it, then wholesale dairymen who dosed it, and the retailer doctored it again.

WHAT MIGHT HAVE BEEN.

In a letter from Mr. Geo. M. Long giving details regarding the animals whose cuts are published on the front page of this issue, the writer finishes his letter as follows:

I just want to add one more word and say that had I been a reader of your paper ten years ago, the price of cotton and high water in the Mississippi River would not worry me as it does just now. I am so situated that the high water gives me seepage and makes my place fit only for grass and dairy cows, and I said to my wife, "If we are damaged as bad this year as last we will have to make Jersey cows out of all our mules, for the mules consume more and pay less than our cows." I wish you and your paper success.

THE hot nights are here and the milk requires the utmost care, if a butter bringing the highest price is to be made. Every hour or even minute that the milk is allowed to remain without cooling, if it is to stand over night, takes from it part of its money value. The ferments that give butter its flavor, as well as those that taint it, are growing rapidly in the warm milk.

Time and bacteria wait for no man—when the milk is warm. So if you don't wish a flavor in your butter that don't belong there, one that the dealer will not want, nor the consumer pay for, cool and aerate your milk and keep it cool at all times when the thermometer is above 60° F., that is, if you expect to make a profit from your summer milk.

PROTEIN AND MILK PRODUCTION.

DR. KITCHEN, in his Comments and Queries on page 474, settles some important problems, and raises others. He has learned as many others before him have learned, in the same expressive school of experience, that one cannot cross breeds as he would mix corn and oats, and reach definite results. He seems, however, to hold, with Prof. Shaw, that the all-round cow—what make-shifts will not people resort to, in order to flatter themselves that they are not in the mire of general purpose?—is a possibility, but with commendable frankness admits that life is too short for him to expect to realize on an investment in that direction.

He, therefore, turns to the established breeds and questions them as to their adaptedness for the special environment of his neighborhood. We are disposed to think he rejects the Ayrshires a little too summarily especially by putting so much emphasis on the difficulty of obtaining them. It has to be admitted, we think, that too many breeders, as well in Great Britain as in the United States and Canada, have bred with both eyes on the show yard, where it has been too much the custom to award all prizes in accordance with a beef scale of points, and neglect those which indicate dairy ability. But there are individuals, and herds, and families that have not been thus bred and reared. We are not permitted to mention names, because by so doing we should be guilty of injustice to those omitted; and if we knew them all, it could hardly be expected of us to advertise them gratuitously. Ayrshires have been advertised more or less in the DAIRYMAN for years, not as extensively as other dairy breeds, and, hence, not only the locations of herds are unknown, but their merits are largely in eclipse.

We cannot quite agree with the Doctor that the Gilmanton farmer cannot afford to feed a balanced ration. We do not mean that he must follow, to the letter, any of the so-called feeding standards, but the present state of knowledge on the subject, does not allow us to believe that milk can be made in paying amounts, without an adequate supply of protein in the feed. The scientists tell us that it requires a daily allowance of seven-tenths of a pound of protein for the simple maintenance of a 1000-pound animal; in twenty pounds of milk there should be about eight-tenths of a pound of casein, and hence, without allowance for the inevitable loss that must occur in changing the protein of the feed into the casein of the milk, we have a demand for one and one-half pounds of digestible protein. If the cow is expected to give more milk, she must have more protein.

It is largely immaterial to the cow where the protein comes from, provided she has the digestive capacity to eliminate it from the feed. We can find it in 25 pounds of clover hay, but only half of it in the same amount of timothy hay. One hundred and twenty-five pounds of oat straw would furnish 1½ pounds of digestible protein, but it would take a good deal of other feed to enable the cow to digest so much straw.

We do not know any reason why soja beans, field peas and even alfalfa could not be profitably produced in New Hampshire. There is, in our minds, more doubt as to crimson clover. This must be sown in the late summer or early autumn, and it is questionable whether it would survive a New England winter. If it will and is cut early, it will make excellent hay. The danger with crimson clover lies in letting the heads become ripe, or nearly so. Too little is known of vetches, at least by us, to justify the putting forth of suggestions. Things of this sort may, very likely, be tried in an experimental way, for a year or two, and thus their adaptability to the peculiar local conditions determined.

The question as to which is the better cow for the farmer, has attached to it irrelevant conditions. The cow whose milking qualities have been properly developed, if of good constitution and adapted to the conditions for grazing, etc., in the locality, is always the better cow. There is no style of breed ing, bringing up, or care that will give us a cow that can transmute carbohydrates into casein. As well attempt to make sugar from salt. A balanced ration does not necessarily imply the use of concentrated feeds, but they are recommended because it is difficult in any other way to supply the cow with sufficient material to enable her to utilize her milk elaborating organs to their normal and economical capacity.

"WARRENTED NOT TO SOUR."

A sample of milk was lately examined in St. Louis, and the chemist returned it with the endorsement, "Warrented not to Sour." It had been so dosed with preservatives that it was warranted not to spoil; embalmed—in fact poisoned so thoroughly that not even that most resistant form of life, a bacterium, could live in it. What chance has a sickly child, when such poisonous food is given it? or, for that matter, an adult with little power of resistance left after a long sickness? Would it increase the chances of recovery to feed a diseased stomach with combinations of milk and formalin, freezine, preservaline and such like?

There are some things, that neither doctors nor professors, can tell us; things which no amount of scientific argument will convince us of.

One of these is the necessity, harmlesness, or desirability of the use of preservatives in our food. We don't want it for ourselves or families, and we decidedly deny the right of any man, be he a Chicago packer or a small milk dealer, to compel us to swallow a daily dose of preservatives, be they reputed never so harmless. Let us have the bacteria alive, and we will attend to the killing ourselves.

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By PROF. H. L. RUSSEL.]

Second Series, No. XXI.

ACCUMULATION OF NITROGEN BY CLOVERS.

If one grows a clover plant in a soil which has been heated, and in which, therefore, the bacteria, including the nodule-forming organisms, have been destroyed, no nodules or swellings will appear on the roots of the plants. The young plantlet may make considerable headway in development, if the soil is a fertile one, but the rootlets will be devoid of these swellings. On a poor soil, however, the growth will generally be scanty, if the soil has been rendered sterile by heat.

Not frequently, it happens that natural soil contains no nodule-producing germs that are characteristic of the clover plant that is used as seed. Perhaps the ground may be so poor "that it won't grow beans," or it may sometimes be much richer, and still not develop various plants of the clover family. The real reason of failure of growth is often not the lack of fertility, but lack of proper nodule bacteria, for with the many species of plants, that belong to this group, there are a number of different specific bacteria that develop best in their own peculiar hosts. Thus, there is a red clover bacterium, that develops best in this plant, and which may not develop, for instance, in the alfalfa. On the other hand, some species of the nodule bacteria are less sensitive. The organism of the hairy vetch will also establish itself in the Canada pea.

This fact accounts for the peculiar property, that soils that may produce a good crop of one kind of legumes, yet may not be available for some other crop.

Take the western prairies. Their natural flora is distinctly leguminous, but in many places, as in the Dakotas, our common red clover could not be successfully cultivated, for many years after the virgin soil was first broken up.

This same fact has been often noted in attempting to introduce relatively new kinds of forage plants belonging to the legume family.

These facts throw a flood of light on many practical questions. If the failure to develop these crops turns on the presence or absence of certain ferments in the soil, why is it not possible to obtain the desired organisms, so that they could be artificially added to the soil in a way that would enable them to establish themselves in the root systems of their proper hosts.

Such a possibility would have been regarded as utterly impracticable a decade or more ago, but having once determined the fundamental laws by which this peculiar property is produced of enriching the soil by growing clovers, it is entirely within the pale of reason, that such an advance step may be made of pratical value.

INOCULATING SOILS.

If continued cultivation, with any species of clover, is apt to enrich the soil as to its fertility, then the soil itself is sure to contain more or less of the specific germs, which find their way into the same from the decay of the plant roots. This being true, it might be possible to introduce the desired germ into any field that experience had shown to be unsuitable for legume culture, by sprinkling or transferring some of the soil from a seeded field to the barren one.

Such a procedure has been attempted and has been attended with very successful results in many cases. At the Alabama station, Duggar succeeded in securing greatly increased yields of hairy vetch and alfalfa by mixing soils from old fields with that of fields on which these plants had never before been grown. At the Kansas station, soy beans had been cultivated for a number of years, but the plants failed to develop nodules. In 1896 Otis secured from Massachusetts a quantity of soil in which this plant had been grown. By adding this to the plat in which the beans were planted, he secured a luxuriant growth and the root systems showed abundant tubercles. In the sandy moorlands of Northern Germany, this method of mixing the soil from an old field, has been successfully employed on a practical scale. According to Salfeld from one to one and a half tons of soil per acre yielded bestresults. Where the inoculated soil was well worked into the ground, thus bringing the contained microbes in direct contact with the developing plantlet, the most marked gain was to be observed.

PURE CULTURES OF LEGUME BACTERIA.

Although the soil method might be successful, it is, nevertheless, cumbersome to transfer so much material when the desired organisms might be isolated and grown in quantities. Naturally this next step was soon suggested, and after many experiments there is now on the market pure cultures of the various legume bacteria that can be utilized much more conveniently. Nobbe and Hiltner have lately succeeded in separating the distinctive forms to be found in a considerable number of different legumes. These can be grown in quantities in pure culture, and so the essence of the soil process of inoculation is carried over into a much more concentrated and convenient form. These cultures are sold under the name "Nitragin," and are used in a manner similar to the "starter" employed in dairy processes. A fairly thorough trial of the different cultures has been made in a number of places. Duggar, in Alabama, found an increase of 89% with hairy vetch, 138% with Canada field pea and 146% with crimson clover.

The value of these cultures has been found to vary considerably where employed under different conditions. In soils that already contain considerable nitrogen the addition of the "nitragin culture" does not increase the crop so much, even though nodule formation on the roots may be aided. Under these conditions the plants seem to take the nitrogen already in the soil, rather than to fix the free nitrogen of the air. Where the soil is deficient in nitrogen, the addition of the bacteria in the "nitragin cultures" stimulates the development of the nodules, which then result in the storing up of quantities of atmospheric nitrogen that later is appropriated by the growing plant.

With our most common legume, red clover, the results have not been as favorable as with other species; doubtless for the reason that the red clover germ is now thoroughly disseminated in much of our arable soil. With the newer varieties of legumes, of which there are a large number that have lately been introduced, the use of "nitragin" has been attended with much better success, for the reason that the necessary organism has not been present naturally in the soil, and it required the initial inoculation to establish the proper conditions for luxuriant development. There can be no question but that the careful way in which these investigations have been carried out, will be sure to yield rich fruit sooner or later. They exemplify, in a striking way, the advantage that agriculture can derive from the teachings of applied science.

A Butter Standard.

The Pennsylvania Department of Agriculture has been advocating the necessity for a butter standard, and has recently made analyses of 100 samples of butter collected in Philadelphia and vicinity. Five grades of butter were tested, including "boiled" or process butter. The average per cent of water was about 11%, of butter fat about 85%; curd between one and two per cent; and salt about 2%. Of the seventy-eight samples of unmelted butter examined, only one contained less than 80% of fat, and only

six did not reach an 83% butter fat standard, to which any dairyman, it is stated, can bring his butter. The percentage of water, according to the results obtained, should not exceed 14% at the very most. The per centage of salt is considered about right when kept below 3%. Two-thirds of the samples contained curd, less than 1.05%. Curd, in all butters, it is stated, should be reduced below 2.05%.

Dehorning Cattle.

ED. HOARD'S DAIRYMAN:—I am a complete, though quite recent, convert to the dehorning of cattle. Since the practice has been so generally advocated by the agricultural press, it has been under consideration, but somehow it seemed a barbarous practice and not worthy anyone short of a butcher or person who is trained to disregard the lives and feelings of animals. The change of sentiment came about accidentally. One of the home herd of Jerseys was afflicted by a horn that turned inward and made an ugly wound where it came in contact with her head. Plainly something must be done with it, so the dehorning problem was brought much closer home than it otherwise could have been.

There had all along been a notion that a "muley cow" was something less than a complete animal. It seemed to us that it had not grown up and that horns would greatly dignify it and give it a standing in the world. I use the word "it" purposely, for horns follow sex so closely in all animals that without them there seemed to be less of that distinction left. But something must be done with the ugly horn, so a sharp, fine toothed saw was bought and the horn was sawed off close to the cow's head. This was a sort of a revelation. There was little bleeding and the cow did not seem to be hurt much. Then a cow with one horn was always a sort of cripple to look at, so the other horn came off. Then it was easy to finish the job and now the herd is innocent of horns and the conversion on the part of the owner is complete.

It has always been held by those who have tried dehorning, that cattle were very much more quiet without their horns and that they could be handled easier, not to mention the less disposition to worry each other in small enclosures. A neighbor mentions an instance where hornless cattle showed a great superiority over the natural animal. The male portion of the family went away one cold winter day and left the cows in the stable. The time for the noon watering came and they did not return, so the housewife turned the cows out and watered them at the pump. It was an odd sight to one who had been used to seeing cows with horns, claiming the right of precedence at meals with all the vim of court ladies. As soon as the water began to run into the long trough every one of the cows came up as though they had been young calves and drank in a row. The watering was a very short matter and the woman did not have to stand out in the cold but a short time. If the cows had not been shorn of their horns they would have had to drink, one or two at a time, and the water would have been much colder that icy day than it was just from the well. Besides, the woman would have had to wait for them. This is one of the many instances where dehorning is valuable to the animal direct as well as to the owner. Now for a breeder who can produce cows without horns! He is wanted.

We are testing the gravity creamer and find it handy, but not without its serious objections. The test was made with no particular desire to adopt the system, but mainly because somebody brought one of the big vats to the farm and asked us to use it. One objection, of course, is the weakening of the skim milk by making it half water. Neither pigs nor calves do well on it. The receipe lately given by Prof. Henry in the DAIRYMAN, for restoring such milk to its normal strength by adding oil meal and middlings, is to be tried, and if it works I will report.

The butter maker complains that she cannot make as good butter from the gravity cream as from the pan-set milk. It is inclined to be sticky and never comes in the granular form that it should. I suppose that this is on account of some difference in the ripening of the cream. Is there not some reader who knows what is the matter and can suggest a remedy? The butter comes reasonably quick. The chances are that the agent will get his "machine" when he comes round next time. It is not worth $9. JOHN CHAMBERLIN.

Buffalo, N. Y.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. FEEDING STANDARDS FOR MILCH COWS.

	DIGESTIBLE NUTRIENTS		
Dry matter.	*Protein.*	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12 to 15.0	0.5 to 0.8

WILL SILAGE LESSEN THE NECESSITY FOR GRAIN?

Does it require less bran and ground feed for milk cows, when feeding ensilage, than without? I am very much interested in ensilage, and am thinking of building a silo, but I do not want to do so unless I can save money on my feed bill. I am milking forty-five cows, and my feed bill amounts to about $40 per month. B. F. J.

Yankton, S. D.

This question might be answered both in the affirmative and the negative, depending altogether upon the direction from which it is approached. The same amount of grain fed in connection with silage will give better results than when fed exclusively with dry fodder. Hence, to produce a given flow of milk, less grain will be required with silage. But all the profit there is in dairying comes from the food consumed, and exclusively from that part of it which is in excess of the amount required for maintenance. Therefore, the more one can get a cow to eat, and not turn the surplus into body fat, the greater will be the profit. Therefore, when we feed silage, we should rather increase than decrease the allowance of grain, and thereby make the greater profit.

GRAIN RATION ON PASTURE.

Enclosed find an article in this week's issue of your paper. Will you kindly find what the ration was the correspondent fed his cows in summer, and publish in your next issue? J. F. C.

Cooperstown, N. Y.

The article referred to was copied, as stated, from the *Practical Farmer*, and was written by a correspondent for that paper. We have no means of ascertaining his name or residence, but if, as may possibly happen, this inquiry should come to his attention, we would be gratified to have him answer it.

Meantime we may say, that the choice of a grain feed to supplement pasturage, may take a wide range. Equal parts bran and ground corn made an excellent summer feed; bran and gluten feed, or bran and a little fresh, sweet cotton seed meal would not be amiss. How much to feed cannot be even approximately estimated. When pastures are at the very best, some good hay may well take the place of grain, but later on grain will be necessary, and the amount must be regulated, in every case, by circumstances. It should be enough at all times to prevent any unnatural shrinkage in the milk flow, and also keep the animal in good flesh. Always the heavy milkers should have more than the light milkers.

VENTILATING A WET CELLAR.

We have a cellar under ground; it is built in the shape of a cistern, ten feet diameter; the top is open, and looks like an arched chimney. We have a small window on the stairway, which leads into the kitchen. This cellar is remarkably cool in summer, and we had no frost in it last winter. Bottom and sides are cemented over brick and whitewashed. The only trouble we have is, that by approaching rain and hot weather the walls sweat so that water will run in streams, which gives much work to keep things from moulding. D. J. M. H.

A case like the above can be easily remedied, if suitable provision is made for ventilation. Of course, where the walls of a cellar are cold, a sudden inrush of warm, moist air will deposit its moisture on the cold walls, and thus make matters worse.

But if an opening can be made from the cellar into a chimney, or in place of a chimney, a six-inch flue made from boards, be run from the top of the cellar to above the roof, the natural draft will slowly take out the moisture in the cellar, and keep it dry.

COW FASTENINGS.

We are going to build another dairy barn, and are undecided whether to put in swinging stanchions or ties. We would like your advice on this, and some cuts, showing where the feed is placed, and whether chains or straps around the cow's necks. We have swinging stanchions in our old barn. It holds 120 cows, and we want to build the new one to hold the same number. Thanking you for your past favors, etc.

KEYES FARM AND DAIRY CO.

St. Louis, Mo.

As between the two devices named, we would prefer the swinging stanchion, largely because of the difficulty of keeping cows in place and clean when fastened with neck chains or ties of any kind. Should prefer a chain to strap of any kind.

It is a question whether any modern barn should be equipped with any kind of stanchion or neckties. There are valid objections to any system of fastening cows that does not provide same sort of a partition or barrier between adjoining animals, and thus give to each one a stall by herself. There are numerous patterns for cow stalls, some patented and some not. In the former class are the Bidwell and Drown stalls, both with adjustable managers and swinging partitions and the animals kept in place with a chain or rope reaching from partition to partition. Others have no manager, only abar in front, and the cow eats from the floor as she does in the field, and a chain or rope in the rear keeps her in place .There is also the "Model Stall" which the senior editor is using with great satisfaction.

In this stall, an inclining rack for holding hay, compels the cow, when standing, to keep well back in the stall, and a bar, two to three inches high, nailed to the floor just in front of the position of the hind feet when standing, *encourages* her to move forward when lying down, and this takes her out of the filth. In this stall the cows are fastened with an ordinary halter about the head.

The DAIRYMAN, in recent years, has published illustrations of several stalls and mangers, and whenever any of our readers can offer new and valuable suggestions in this line, we will take pleasure in having drawings and engravings made for publication in these columns.

A FLORIDA FEEDING PROBLEM.

I am feeding my cow wheat bran, corn meal and cotton seed meal, and mixing cotton seed hulls with this. Please give me a ration with these constituents. I feed crab grass hay when I have it, but my last year's crop is exhausted. SUBSCRIBER.

Ormond, Fla.

Of course, it is well established that cows can live and yield some milk if given plenty of grain and all the cotton seed hulls they will eat for roughage; but this is very far from being an ideal ration, or, indeed, a suitable ration. We do not have cotton seed hulls at the North, but we do have their counterpart in the overripe straw from our grain fields, and the dried, weather beaten, woody remnants of the corn crop in the stalk fields. Progressive and prosperous dairymen have learned that it does not pay to limit cows to such forage. They have found that, even with the best of hay, it is expedient to have some succulent feed through the winter and during the summer drouth. Corn silage furnishes this with least expense and greatest satisfaction, but, in its absence, roots serve a good purpose. Just what can be grown in Florida, to best advantage, we cannot say, but should suppose that kafir corn and cow peas or soy beans would be adapted to the soil and climate there. These can be made into excellent silage, or cured for hay.

So much by way of suggestion for the future. From the feeds available for present use, we advise mixing by weight, two parts bran, with one part each corn meal and cotton seed meal, and feeding from four to ten pounds per day, the amount to each cow to be graduated according to her ability to respond at the pail. It is supreme folly to feed a cow that has been milking six, eight, or ten months, as one would feed the same cow soon after freshening. Then there is the difference in cows. One cow may be able to turn ten pounds of grain to useful purposes, where another would grow fat on half that amount, and fattening the milch cow is wasting feed.

In addition to a grain allowance, as above, give all the hulls or other roughage each cow will eat.

AN ILLINOIS FEEDING PROBLEM.

Please give ration for milch cows when desirous of feeding corn fodder and timothy hay. Grain prices as follows: Oats, 25c; corn, 30c; bran, $13; O. P. oil meal, $22; gluten, $16.

Also ration when desirous of feeding small amount of corn ensilage with the timothy hay and corn fodder, grain being same as above prices, taking into consideration that plenty of oats and corn are raised on the farm and wish to make ensilage last as long as possible. SUBSCRIBER.

Batavia, Ill.

Oats at 25c per bushel will cost, when ground, about $18 per ton, and corn at 30c, fully $13. The several grains named, if of average quality, will contain the following percentages of digestible nutrients.

	Dry Matter.	*Digestible Nutrients*		
		Protein.	Carbohydrates	Ether Extract
Oats	89.0	9.2	47.3	4.2
Corn	89.0	7.9	66.7	4.3
Bran	88.1	12.6	38.6	3.0
O. P. oil meal	90.8	29.3	32.7	7.0
Gluten feed	92.2	20.4	48.4	5.0

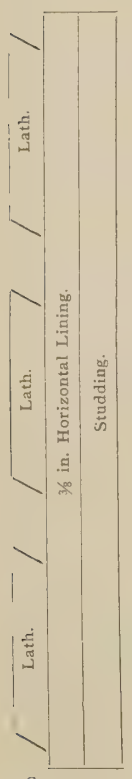
With timothy hay, corn stover and silage, the principle nutrient to be sought for in the grain is protein, and hence the feeding value of the above grains will be in proportion to the amount of digestible protein in each. It follows, therefore, that it would be profitable to sell the corn and oats at the prices named and purchase bran, oil meal and gluten feed. It is true that bran is not relatively as cheap as either the oil meal or the gluten feed, but it is essential for best results in digestion that the grain portion of the ration shall not be too concentrated, and bran, in addition to its actual feeding value, is the best diluent for the more concentrated feeds—and the lighter the bran, the better will it serve this purpose.

Taking all the elements of the problem into consideration, we suggest for trial, and as an average for the entire herd, some receiving more and others less, the following daily allowance:

FORMULA FOR RATION.	*Dry Matter.*	*Digestible Nutrients*		
		Protein.	Carbohydrates	Ether Extract
12 lbs. timothy hay	10.42	.34	5.21	.17
10 lbs. corn stover	5.95	.17	3.24	.07
5 lbs. bran	4.40	63	1.93	.15
4 lbs. gluten feed	3.69	.82	1.94	.20
1 lb. O. P. oil meal	.91	.29	.33	.07
Totals	25.37	2.25	12.65	.66

When silage is fed, reduce the hay and corn stover at the rate of about one pound of the dry fodder for each three pounds of silage. The rule in regard to coarse fodder is to give only so much as each cow will eat with good relish. Put before her all she will eat, and no more, be the same more or less.

Give a little salt every day.



Silo Construction.

Not long since the writer of the subjoined letter, visited Fort Atkinson, for the purpose of conferring with Mr. Goodrich and the Editor of HOARD'S DAIRYMAN, in regard to the best method of constructing a silo, and the general principles to be observed. He is a man of large business experience in many ways and quite accustomed to reach conclusions for himself, when he has the attainable facts at hand. In other words, he thinks for himself, and does not expect others to pronounce as to the particular kind of a structure, machine or implement that will be the "best" for him.

In the matter of the silo, he has reached very definite conclusions, and HOARD'S DAIRYMAN cannot say that he has chosen unwisely. When the structure is complete, we wish he would give, for the benefit of other readers, the full details as to cost, with prices of materials used, and from time to time report on its properties, and the degree of satisfaction given.

The letter was written to Mr. Goodrich, and reads as follows:

I mail you to-day, a specimen of lathing for cement plastering inside a wooden, round silo, as I suggested in our recent conversation. A German mason, who learned his trade in Germany, tells me he is sure it will be all right by using two parts of good sand and one of Portland cement. The lath is very cheaply made, on any saw table, with thin saw, and any inch lumber not too knotty, or very shaky, is good enough, and will handle better in short lengths, necessarily tied in bundles as made. Any damage to plastering of this kind, can be repaired as easily as anything else could. If action of silage on it should be injurious, I see no reason why surface may not be treated with something acid-proof, but do not much fear such difficulty.

SECTIONAL VIEW.

My idea is to build part above ground, on general principles, as advised by Prof. King, except inside finish of this lath and cement plaster over one thickness of three-eighths inch boards, but go six to ten feet below ground also.

I understand you knew of a ground silo with a superstructure, the below ground part plastered directly on the clay surface of hole. Am I correct? If so, how is the superstructure supported? In such a case, seems to me there should be, at least, four columns of stone or brick inside, face flush with face of excavation, from bottom of holes to sills of superstructure, and at least, a foot of something similar all around under sill; in ground at all liable to heave by frost, this also would need guarding against.

Is silage ever salted as put in? Is it desirable, if so? Unless it injures keeping quality, I should think it would be a good way to be sure cows are regularly and sufficiently supplied with salt

When through with it, you may hand this and sample of the lathing to HOARD'S DAIRMAN for any use it may wish to make of them, including criticism.

Warrens, Wis. W. A. BARBER.

REPLY BY C. P. GOODRICH.

In reply to Mr. Barber's questions will say: The particular silo to which I referred is 18 feet in diameter and 30 feet deep in the ground, with a superstruction of wood of 8 feet. It is inside the barn where water and frost will not affect it, and the ground is of such a nature, such as they have on some of the bench lands near the Missouri River, that even if it did freeze it would not "heave." There is no sand or gravel, but it is firm and the earth walls of the silo can be made perfectly smooth and good to plaster cement onto.

Under such conditions all that is necessary to support the light superstructure is to make the earth part just at the top, a few inches wider, so that a thicker coat of cement can be put on. There lay one or two courses of brick around for the sills to rest on.

Where the ground is such as is usually found in Wisconsin, in places where the earth walls can be made smooth enough to admit of being plastered with cement, I think the suggestions of Mr. Barber as to providing support for the superstructure are excellent, especially where the greater part of the silo is above the surface of the ground instead of below it.

I have never known of silage being salted when put in. I am inclined to think it is not desirable to do so, not because it would affect the keeping qualities one way or the other, but because I prefer that cows should have their salt separately every day; then each one could take just as much as she required. Some cows want an ounce a day and some two ounces. If it was salted as put in, it would be pretty fine business to get it so evenly distributed that no cow would not, on some days, be compelled to eat much more salt than was good for her if she ate her full allowance of from thirty to fifty pounds of silage.

The sample of lath which is sent is what is called by some, diamond lath. It is nailed on the inside lining horizontally without any furring. The lower edge of a strip of lath is beveled off on the front side and the upper edge of the strip below it, is beveled on the back so that the cement that goes in the crack between the laths forms a sort of hook to hold it firmly on. This looks as though it might be an improvement over the common square edge lath. But after all I do not see what there could be to make the cement plaster come off even with common lath. There can be no pressure from behind it and in a round silo it is in the form of an arch, which, if the coat of cement is heavy enough, would prevent its coming off. C. P. GOODRICH.

Forage Crops for Cows.

[Paper read at the North Carolina Dairymen's Association at Concord, by MR. C. C. MOORE, of Mecklenburg County.]

"There is a something that draws a man to dairy work; that it is that induces one to stick to a work that is so exacting and that requires 365 days work each twelve months, counting Sundays, Thanksgiving, 30th of May, July 4th, Christmas and New Years. I do not know what holds us, but it is true that once a man gets into the work he is a prisoner for life.

"I, as a boy, spent my days selling goods and book-keeping. During my business life at merchandising, I had the financial management, for five years, of a firm doing a business of $120,000 yearly; at times I thought it impossible to pull through panic years and while doing this work I thought it the hardest to manage to a success, of anything I should ever attempt. That was easy compared to my work for the past nine years. I have found more tight places to pull over in a little dairy business, aggregating $8,000 per year, and harder work to get over them than I found in all my former occupations; because of the multitude of leaks found in dairy work.

"One great cost of this work is feeding. A dairyman must study the feed question and just as long as he makes all food needful there is hope of success. To buy cow food to produce milk or butter will break quite a rich man.

"What shall a man plant to produce food for milk cows? I speak only from experience, so far as feeding for milk is concerned. Butter making may require different feeding. I do not make butter, so cannot speak on that line.

"Corn is my favorite, it is at home and will produce more cow feed on any land than any plant I have tried. We plant every week or ten days from March 1st to August 1st, if land is in condition.

"Our first planting in March is of improved Golden dent and Gentry Early Market. Either variety will grow to good feeding conditions in ninety days. Owing to the wet spring we did not plant this year until April 22d. Gentry planted that day is now ready to tassel out althought the land has not been wet since planted. We spend much time preparing land for crops and think the extra work is good pay.

"Plant with drill in rows 3½ feet; plants in drill six to ten inches. When land will work, the Thomas harrow is dragged over every week until corn is six inches high. If a rain falls the harrow is run over as soon as land dries enough to hold up a horse, afterculture is with Globe's cultivator, unless by reason of rain the grass starts on row; a small plow is then used to cover the grass.

"We try to plant corn every Saturday. This plan gives soiling for cows from July 1st to November 1st; to feed we cut three or four inches from ground with a short handle hoe, at barn we cut to one inch length and feed about two bushels to a cow daily. If weather is favorable the corn harvester is used for half day, cutting enough to feed ten days.

"Sometimes a lot will ripen faster than we feed; we cut and shock for winter feeding.

"Corn for silo is planted very much as for soiling except that we plant nine to ten quarts soy beans per acre in same rows with corn at last working. Peas, of running variety, are sown. The corn harvester clips everything on the row so that we get for the silo, corn, beans, peas, weeds and Means' grass. Where other farmers would strip fodder, we cut for silo, finding silage from corn nearly ripe to be better for milk-making that that cut at roasting ear stage. If we had to give up all forage plants except one, and had to choose that one, corn would be our choice.

"A variety is best, however, and we project with a lot of forage plants. For summer no food we have found is better than sorghum. Cows are fond of it, the milk is sweetest I ever drank, the crop is easy grown, not at all checked by drouth, and if planted in April two feedings are had from one planting.

"Milo maize, kaffir, pop corn and pearl millet are al good and are cultivated as the sorghum crop. The cows enjoy an unexpected change; for their pleasure we grow several of these crops each year—any of which may ripen ahead of consumption is cured for winter use.

"Sorghum and peas grown together is fine feeding. We take an acre on which forty or fifty loads of manure is spread, before plowing, break with Hancock rotary plow, five horses; follow with sub-soiler, two horses, roll down flat, sow three pecks peas, one half bushel sorghum, cut in with disc harrow, four horses, drag twice with Thomas harrow. Just try this one time if you want feed. When sorghum leaves are well spread we begin to feed, and we always see an increase in the milk flow.

"Peas and German millet produce our favorite winter forage to go with silage, on a clean, mellow seed bed. We disc in three pecks, and roll. When peas begin to sprout ¼ bushel of millet is sown and bushed in—the weeder is nice for that. To grow a big crop use manure liberally. Cut for hay when millet blooms—never mind condition of peas. We windrow same day we mow, let lay twenty-four hours if hot weather, then put in barn from windrow.

"If I can have plenty of silage and plenty of pea-millet hay all winter I can make milk and not be dependent on cotton oil mills or flour mills. Both are greedy concerns, ready to grab every dollar the milk man gets.

"I will not mention silo or silage. There are present those who can tell all about this great plan for winter feed. I do wish to speak about the dry corn fodder. Unless a farmer has more forage than he can haul to the barn or stack, by all means the corn should be cut close to the ground at fodder pulling, stack on tripod, leave until cured, husk corn off and feed—it will surprise any farmer to see cattle, horses and sheep pick at the corn stover for hours after having had a full feed in barn.

"We cut corn with the McCormick harvester, husk and cut with husker, feed the cut stover with silage during winter or mix with bran and meal, and feed as mixed feed, or dry—it is good any way.

"I have seen tons upon tons of stalks and fodder left standing in the corn fields after corn was gathered and by December, and all winter, and even as late as June, have seen farmers who discarded such excellent fodder, haul cotton seed hulls six to ten miles and pay $3 to $4 per ton for it. There is a leak through which many dollars from farmers pockets is flowing to the bank account of the American Cotton Oil Co.

"If all the corn growing now in Cabarrus county, could be saved entirely, the new oil mill would find few farmers to buy their hulls.

"Just for the 'big' of the thing I throw away $10 to $15 each year for red clover seed. I read so much about red clover, and in fact, years ago I had such fine crops to grow that I just cannot drop it. However, the crop has failed with us for six years. Valuable as clover is, I am not convinced that it is better or more profitable than pea-millet hay. We have concluded to drop clover and sow peas. Sow at every opportunity and on all available land from May 1st to July 20th. If we do not cut a vine the crop is a paying one.

"At Double Oaks we usually feed pea vines August, September and October. One or two acres are mown and raked when wilted and put in large cocks. As needed we haul to cows. Have had such out in three days rain, but suffered no loss. Cutting a lot at one time is a saving of time, besides the wilting of vines is an advantage, as the milk will not taste so strong of the pea flavor.

"While red clover has failed for us, we have had great success with the crimson. We like it better each year and sow larger fields than we did before. We have learned the value of this plant. We seed crimson clover with oats—sow in August or September—one peck of crimson to one bushel of oats per acre. If land is moist at time of sowing we always get good results. We sow with rye, also with millet, and last August, sorghum was tried—½ bushel sorghum seed to one peck clover. Cut sorghum as hay about the middle of October. When raked up we found a fine stand of clover, which went through winter safe and make a splendid growth in the spring. We shall try same plan this year. Cut clover when coming in bloom—a tender, sweet hay is secured and all stock are fond of such. Lucerne is appreciated for an early cut for spring feeding. The plant suffers in dry summers but we find much value in the crop when we seed with oats in September—

"Keep to Your Place and Your Place will Keep You."

Without good health we cannot keep situations nor enjoy life. Most troubles originate in impure blood. Hood's Sarsaparilla makes the blood rich and pure, and thus promotes good health, which will help you "keep your place."

Never Disappoints

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,
67 Main Street, - Cortland, N. Y.

even if but two cuts are made from one seeding it is good pay. The finest hay can be made by cutting lucerne and oats at time oats is in dough state—the crop cures a green colored hay and is soft and tender. On nicely prepared seed beds, sow one bushel of oats, cover with disc harrow, then sow ten or eleven pounds of lucerne, cover with cedar or stiff brush.

"Lucerne seed is not so high in price as it was some years ago. Any farmer can seed one or two acres at a small cost.

"If we have a corn field not to be sown in wheat or oats, we seed down with a mixture of wheat, oats, barley and rye, sowing in August, if possible. From this we get winter grazing for young cattle and find it a great help to the young cattle.

"All milk men know the value of an early crop in the spring—the cows look for an early bite, and always pay for the same in an increase of milk.

"For the first cutting we find rye and crimson clover the smartest crops—to induce to do their fastest growing, we select a spot of land which warms up early in spring, on this we spread twenty-five two horse loads of cow manure per acre and plow under, sow our seed, then on top put on twenty-five loads horse manure (all manure is put out with Kemp distributor); the horse manure serves to keep young growth warm and when winter breaks, the crop is soon ready for cows. Oats and lucerne come next; then wheat, surely is a fine milk producer. Since we learned the value of green wheat we feed great quantities, sow two bushels of wheat, one peck crimson clover per acre. This combination makes a fine soiling crop.

"About November 15th to 20th we try to sow one bushel Canada field peas, one bushel oats and one bushel barley per acre. The three kind of seed stand our average winter all right, if a very hard winter follows we sometimes lose the pea crop, but success is more frequent than failure. When all go through the winter we get a heavy cut either for green feed or for curing for forage.

"If weather in January is favorable we sow the same combination, but later than February 10th it is not advisable to sow Canada peas. Plow in peas pretty deep, five or six inches is our plan, cover barley and oats with disc harrow, or put in with grain drill.

"For my use and business, I am convinced that land brings more money to me when used for producing forage than is the case when I try any other crop. Buying the rough food for horses or cattle, is an expensive business, both in money paid for it and the hauling. I can excuse a man with 60 or 100 cattle for buying forage, but the farmer who has ten or twenty head to feed, needs to figure a little before he neglects the forage crop to enable him to produce larger money on sale crops."

Silo Experience.

A Michigan Dairyman on Silos and Silage.

ED. HOARD'S DAIRYMAN:—In response to your request for silo experience, I will state that for the last five years I have been filling silos and feeding ensilage.

My silos are four in number, two for winter feeding, which are 8×8 and 9×9, and two for summer feeding, each 6×6, all being 22 feet high; they are all square, and built on the same pattern—they might be called "cheap silos." I used horizontal studding, 2×8 lapped and spiked at the ends, sided up and down with a good quality of well seasoned, white pine flooring, which has previously been painted both sides with one coat of Venetian red and oil.

Only one thickness of siding is used and no paper. These silos cost from $30 to $50 each, to build.

I am going to build two more on another farm next month. They will be of the same construction as those I have built, because these silos have been perfect with me, and I see no reason for putting in any more money in a silo than is necessary to get good results.

My objection to round silos is, that placed in a barn, there is a large amount of waste room around which cannot be used, and they are more expensive to construct.

In each corner of my square silos I nail in 2×6 plank properly beveled; thus rounding the corners, and with five years experience I have not lost ten bushels of ensilage, except that which necessarily spoils on top, I attribute this, in a large degree, to the care I take in filling. I always keep two men in the silo, one constantly throws the ensilage upon the sides of the silo, keeping the sides three feet higher than the center.

The other man's instructions are to keep tramping constantly upon the edges of the silos, giving a little extra tramp in each corner

I never have any spoilt ensilage in the corners. For three mornings after filling, I give the ensilage a thorough tramping, then wet it down thoroughly, using no other covering.

I commenced feeding the silage last November, and have fed it every day since, and am now feeding one-half bushel twice a day to each cow, which they eat greedily; and they have good June grass pasture. I still have one small silo which I have not opened.

I have wintered twenty head of Jerseys, and am now milking twelve cows, and the corn necessary to fill these silos was raised on four acres of creek bottom land. The bottoms of my silos are cemented. Seven similar silos have been built by my neighbors and all are giving perfect satisfaction.

The details of construction and picture of my silos can be obtained in special Silage Bulletin Number 6, issued by the Michigan State Experiment Station, Lansing, Michigan.

The construction of my silos and methods of filling the same, having proved so nearly perfect, I have no desire to try any further experiments.

Ensilage is cut in one-half inch lengths by a steam thresher engine. Last August I filled the four silos mentioned in two days, and drew my corn one mile.

J. W. HELME.

Lenawee County, Mich.

Notes From Sigworth Farm.

Drouth in Pennsylvania.—Packing Summer Butter.—The Gravity Separator.

ED. HOARD'S DAIRYMAN:—Our spring was wet and cold, so our planting was late, and on account of bad weather, a good deal of the corn failed to grow, and when it got more favorable weather, about June 5th, there was a good deal of corn planted in, since when, until to-day, July 17th, we have had but two light showers, neither of which was sufficient to soak to the corn roots. Now it has rained for twenty-four hours, a steady soaking rain. By oft repeated cultivation, we have saved our corn crop, and it will make a fair yield.

Hay is about all made, and was not more than a half of an average yield. New meadows were very weedy; pastures had dried up so that cows, where dependent on pasture alone, had shrunk one-half on their milk; hay is selling in our local market, higher than for years at this time, and butter is retailing at twenty cents per pound against fifteen cents, at same date last year.

Our butter is about all contracted for at twenty-two cents per pound by the year. We aim to make as much in winter as in summer, but when we have an over supply in summer we do not sell way down at low prices, but pack, and find very ready sale in winter, for it.

Our method is (we are always very particular) to be sure the buttermilk is all worked out, salt a little heavier, work moisture out well, pack in two to four gallon jars, well cleaned and thoroughly scalded; cover with a layer of cheese cloth, and put on two inches of salt on top of cloth, and set jars in coolest, airiest place in cellar. Then in winter we churn it through fresh buttermilk, and prefer it for our own use, to winter butter.

The outlook for dairymen has not been better for several years, and, Mr. Editor, keep on hammering at butter frauds, and all frauds in general.

Just now our country is suffering from an attack of the jaw of the gravity separator man, and some of our farmers are investing seven dollars in a three dollar can, with the privilege of feeding milk that is half water; but the agent tells them one gallon of this mixture is as good as one gallon of pure skim milk. Those are the fellows who cannot afford to take a farm or a dairy paper, but invest in all fakes. Truly the farmer is the easiest hoodwinked and bamboozled man in existence. But we have the assurance, in the increased circulation of such papers as the DAIRYMAN, and a host of good farm papers, that this condition will soon change. So mote it be.

Franklin, Venango Co., Pa.

A Dairy Barn.

Mr. L. D. Snow, prominent a dairyman of McLeon, Ill., has just completed a barn for dairy purposes, which contains some interesting features.

The barn is 40 by 80 feet and has room for forty-two head of cows, beside a stall for calves and room for fifty tons of hay, and sufficient storage for other foods. A feature of the structure is a feed trough, which is also used as a water trough. It is V shaped and set into the feed floor in front of the animals' head. The water is let into the trough at the end by means of a pipe, and when all of the animals have been watered, the water is shut off, and the trough used for placing the feed. Another new feature of the structure is a means of ventilation. A cap roof or comb to the roof, allowing an air passage of six inches. Directly beneath this is a passageway to the floor of the barn is a row of loose boards or traps, which can be opened and the air draft goes directly from this trap to the roof and out. The draft in this way does not blow over the animals in the barn chilling them, but passes directly in front of their heads, and upward furnishing fresh air. Mr. Snow now has room for eighty head of cows.

Seeding for Fall Pasture.

To a Holmen, Wis. correspondent of the Wisconsin Experiment Station, who writes inquiring about the best seeding for wheat stubble for fall pasture, Professor Henry says:

"By all odds the best crop for this purpose is barley, sown at the rate of two bushels of seed per acre. The barley plant stands considerable freezing in the fall without showing injury. In this particular it is much superior to oats or wheat. In favorable falls, barley sown after grain harvest will form heads and occasionally ripen the grain. One should not look for a second crop in this way, however, but when the young plants are half knee-high turn in the cattle and graze off the field as though it were a pasture lot. I strongly urge farmers who can do so to try a pasture field of summer-sown barley this fall. Rye is next to barley for fall pasture, and since it lives over the winter is sometimes more satisfactory, since it will again furnish pasture in the spring.

"At the University farm at the present time, we have two fields sown to oats, with grass seeding additional. We have had sheep pasturing on one of these lots and dairy cows on the other. In both cases the pasture has proved a success.

"Farmers should learn the value of wheat, oats, rye and barley, especially the last two for pasture purposes. In every case sow clover and timothy with the grasses in the hope of getting a good stand of these. This may not always be best, but the venture is worth the cost of the seed.—*Wisconsin Agriculturist.*

Did you ever See a Snow Storm in Summer?

We never did; but we have seen the clothing at this time of the year so covered with dandruff that it looked as if it had been out in a regular snow-storm.

No need of this snowstorm.

As the summer sun would melt the falling snow so will

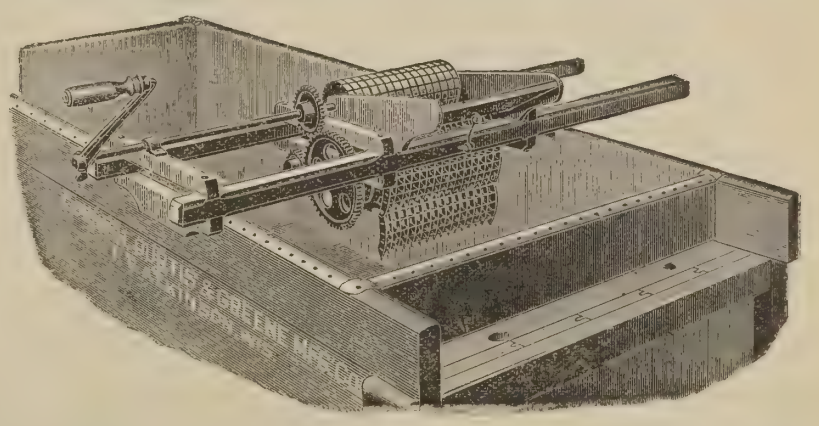
Ayer's Hair Vigor

melt these flakes of dandruff in the scalp. It goes further than this: it prevents their formation.

It has still other properties: it will restore color to gray hair in just ten times out of every ten cases.

And it does even more: it feeds and nourishes the roots of the hair. Thin hair becomes thick hair; and short hair becomes long hair.

We have a book on the Hair and Scalp. It is yours, for the asking.



If you do not obtain all the benefits you expected from the use of the Vigor, write the doctor about it. Probably there is some difficulty with your general system which may be easily removed. Address,

DR. J. C. AYER, Lowell, Mass.

Some Elegant Stock Ranches

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentation to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, **$25.00**

CORNISH, CURTIS & GREENE MFG. CO., Fort Atkinson, Wis.

Inventors, Manufacturers and Dealers in Everything Pertaining to Butter and Cheese Making.

Agents for DE LAVAL ALPHA SEPARATORS.

THE creamery men in Southern California have organized themselves into an association for the purpose of promoting their interests in every possible way, but especially in the matter of securing stable and profitable markets for their butter. An effort will be made to thoroughly canvass Arizona and New Mexico in this behalf.

SEPARATOR skim milk is one of the best possible foods for calves *if* it is fed warm, fresh from the separator, and clean.

There is not a worse food for calves on the face of the earth, than separator skim milk *if* it is old, stale, cold and dirty.

The fact that some dairymen feed it in the first condition and others in the second condition, accounts for the varying opinions that we hear expressed concerning the value of separator milk. According to the quality of the skim milk fed, so will your calves be. Which class of milk do you feed?

Roof for a Stave Silo.

ED. HOARD'S DAIRYMAN:—In connection with the description of the stave silo at Purdue Experiment Station, recently reprinted, the following description of the roof, put on at a cost of $10.50, after the filling, may not be amiss.

The past year's evidence and growth in silo experience, suggests that in some cases, a roof may not be a necessity, especially where little snow falls. Still many will want an inexpensive roof on their silo.

In the accompanying sketch the 2×6 A, A. were p'aced on edge and toe nailed to the top of the staves they rested on. The projection is for supporting the carrier at filling time. They are tied together by the short pieces E.

The roof is in three sections G, H and I. G and H are hinged to the frame A, A and may be tipped up when the silo is nearly full, to allow filling to the top. The narrow middle section is light enough to lift off on either side, and leaves the opening for the carrier to deliver into.

On the frame work B, B and C, C cheap sheetingboards are nailed. This is then covered with tin, soldered joints and painted.

The section should be fastened down by means of staples and hooks, or other device; the hooks are used on this one. On the inner edge of G and H, 2×2 inch strips K, are nailed; close to these are placed similar strips J, to which the cross boards are nailed, forming the section I, of the roof.

The tin on the section I should come over the edge on to J. On the other sections it should run up on the side of K, making a water tight joint.

The sections, G and H have a slope of nearly 3 inches, being the difference in height of A and C. C is notched at the outer end one inch.

Lumber	$4.00
Tin put on and painted	$6.00
Hardware	.50
	$10.50

This silo was opened at midwinter. The ensilage had kept in excellent shape; no spoiling whatever about the sides or doors. The last of it is now (June 28) being used to supplement pasture.

H. E. VAN NORMAN.

A CHEAP ROOF FOR A STAVE SILO.

Handling Machine Cut Corn.

ED. HOARD'S DAIRYMAN:—Last year, John Gould told us how he shocked his corn that was cut and bound by a machine; this was the dry fall of '97. We would like to know if he shocked the same way last fall, and with what success. C. B. C.

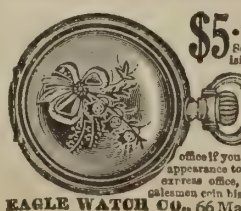
North Manchester, Ind.

ANSWERED BY JOHN GOULD.

All of our overplus corn fodder, especially a five acre field of husked corn was put up "this way," the wet fall and winter of 1898-9, and the success was fully as great, even more so, because the shocks could not fall down or get leaned very far out of perpendicular.

The stalks in the field corn lot were sold, as we had no use for them, and the buyer allowed them to stand there until into March before he drew them, and then pronounced them the finest he had fed through the winter. The whole secret in the matter is to reverse the bundles in the X, so that a top covers the butt of the bundle before it, and so on up as far as the cross piling goes, and when filling into the corners or angles, go round and round, so as to intermix the tops, as they are made more rain proof I think by this plan, than where a corner angle is filled at once.

A couple of shocks of silage corn were purposely left in the field, and only removed when plowing, last May, and they looked so nice and bright, that a neighbor begged them



Stock, Dairy, Hay and Hop Ranch.. 1100 acres consisting of 800 acres cleared, alluvial land, and 300 acres in timber and brush. On Yakima River, Yakima Co., Wash.; abundance of water and independent water distributing system. Close to N. P. Railroad, near foot hills and outside Range. Mean temperature, winter (Nov Feb.), 31 degrees, summer 59. Annual rainfall 10 inches. Alfalfa 3 and 4 crops a year. $45,000. 25 per cent cash, balance in annual installments. This property pronounced by independent judges to be unique for a Stock and Dairy farm. Can be sold in 80 acre tracts.

for horse feed. The bottom bundle was pretty badly soaked but that was all. The mice and squirrels had husked out the corn grains, but were otherwise thankful for a good protecting roof over their bodies. We made about forty to forty-five bundles of tall silage corn into a shock. With shorter field corn fodder it is not possible to make them so large, though by breaking two bundles across the top, we had good success with the larger ones.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The Board of Trade opened with a small offering of butter this week; but 5,700 pounds being put on the board. One buyer offered 18 cents, but the manufacturers refused to sell, and then when the Call Board closed, no orders were reported. The Quotation Committee quoted the market steady at 17½ cents. The total output of the week was reported as 756,000 pounds.

Former markets:

July 17, 1899, 96 tubs sold at 18c.
July 25, 1898, 56 tubs sold at 17½c.
July 26, 1897, 300 tubs sold at 14½c.
July 27, 1896, 915 tubs sold at 14@15c.

New York butter steady at 18 cents.

Elgin, Ill., July 24. H. C. B.

Saving Fertility.

The effect of continual cropping in the exhaustion of soil nitrogen has been made the subject of study in planting peas, buckwheat, oats, etc. The results of the experiments show that only the leguminous plants were able to utilize the nitrogen of the air. An increase was noticeable in the yield of each succeeding crop of peas, while with the non-leguminous crops, each succeeding yield was poorer than the preceding one. The experiments simply show, what every farmer knows, or ought to know, that planting clovers, cow peas, vetches or any legumes, tends to constantly improve the soil, while cropping with non-leguminous plants, such as corn and wheat, unless fertilizer of some kind is used, constantly depletes the soil. Vast amounts of fertility can be saved to the soil, by the liberal planting of leguminous crops—*Wisconsin Agriculturist.*

DAIRY MARKETS.

ELGIN, Ill., July 24—Butter—95 tubs offered; 18c bid; no sales; committee reported steady at 17½c.

CHICAGO, Ill., July 24.—Butter—Creameries, extra, 17c per lb; firsts 16@16½c; seconds 14@15c; dairies, fair to choice 12½@14c; fancy 15c; imitation creameries 12@14c; ladles, extra 13@13½c.

Cheese—Full creams, Young Americas quoted at 8¾@9c per lb.; Twins 8½@8¾c; Eastern makes, Twins 8⅝@9c; Cheddars 8¾@9c. Special Lines—Swiss, new 9@9½c; Brick, choice 8@8¼c; Limburger, new 8@8½c.

Eggs—Strictly fresh stock, loss off, cases returned, 11½c; candled, cases included 12@12½c.

Bran—Sales at $11.75@12.00 per ton.

Cattle—The choicest grades of beef cattle ruled strong to 10c higher, while all other grades were no better than steady. The general market was active, and an early clearance was made. Most grades of beef cattle are 20c higher than a week ago, and about that much higher than a year ago, when the top was $5.65. A load averaging 1,588 lbs. sold to-day at $5.80, with a dozen loads at $5.75. Most of the beef cattle sold at $5@5.60, with comparatively few below $4.75; corn fed Western steers $4.50@5.70; distillery steers 1,076@1,342 lbs. $4.90@5.45; straight Texas steers $4.00@4.80 with thin grassers 524 lbs. $3,25; Texas cows $3@3.40. Texas calves 167 lbs. $3.60. About 1,000 Texas cattle sold at steady prices. Native cows sold principally at $3@4; heifers largely $4.10@4.70; distillery bulls 1,240@1,272 lbs. $4.50; stockers and feeders $3.50@4.65.

MILWAUKEE, Wis., July 24—Butter—Creamery—Fancy prints per pound 18c; extras per pound, 17½@18c; firsts 16@17c; seconds 14@15c; imitations per pound 14@15c. Dairy—Selections per pound 14 cents. Market unchanged and moderately active; receipts 16,230 lbs.

Cheese—American full cream—New, choice to fancy, 9@9½c. Brick—New per pound, choice, 8@8¼c. Limburger—New, choice per pound 8@8½c. Swiss—Drum, choice, 12½@13c; new block, choice, 10@10½c.

Eggs—Fresh per dozen 11½c; loss off, cases returned. Market stronger and more active; receipts 294 cases.

AVOCA, Wis., July 24—Offerings on Lone Rock and Muscoda Dairy board to-day were 1,577 boxes. Market active and all sold at 8¾@8⅞c for Twins, and 9c for Daisies.

FOND DU LAC, Wis., July 24—Offerings 700 Twins, with free sales at 8⅞c.

HORTONVILLE, Wis., July 13.—Cheese—Offering on Board to-day were 440 Cheddars and 1,068 Twins. Sales: 326 Cheddars at 8⅝c; 2 6 Twins at 8¾c; 500 Twins at 8⅝c. Ruling price: Cheddars 8⅝c; Twins ⅝c. Market active.

BRILLION, Wis., July 21—Sales at Brillion Dairy Board to-day 100 Young Americas, 8¾c; 445 Young Americas, 8⅝c; 1,394 Daisies, 8⅝c; 849 Twins, 8⅝c.

PLYMOUTH, Wis., July 18.—Sales today, 1,243 twins at 8¾ c; 840 Americas at 8¾c and 250 Americas at 8⅞c, market firm.

SHEBOYGAN FALLS, Wis., July 19.—There were 1,240 boxes of cheese offered on the Call Board to-day, and all except two lots were sold, as follows: 100 cases Young Americas at 8¾c; 731 at 8⅞c, and 214 boxes Twins at 8¾c.

MANITOWOC, Wis., July 19.—Offerings of cheese at the Dairy Board of Trade to-day were: 800 boxes Daisies, 950 boxes Twins, 900 boxes Young Americas. All offerings sold at 8½c.

BERLIN, Wis, July 15—Cheese—The offerings on the dairy board to-day were 341 Twins and 22 Cheddars. All sold at 8½c.

CHILTON, Wis., July 12—Cheese—The sales reported on the dairy board to-day were 520 boxes Twins at 8¾c and 640 cases Young Americas at 8½c.

APPLETON, Wis., July 13—Cheese—On the Appleton call board to-day the offerings were 135 Cheddars and 396 Twins. Sales 180 Twins at 8¾c. Market brisk. The board will meet hereafter at 4:30 p. m.

NEW YORK, July 24—Butter—Creamery Western extras, 18c; firsts, 17@17½c; state extras 18c, firsts, 17@17½c.

Cheese—State full cream large colored or white choice, 8½c; small, 8¼@8¾c.

Eggs—State, Pennsylvania, and Western, 15@16c.

BOONEVILLE, N. Y., July 16.—Cheese—On Board of Trade here Friday 40 boxes of colored cheese sold for 8⅛c: 525 boxes at 8¼c; 150 boxes at 8⅜c; and 100 boxes at 8½c. There were 200 boxes large white sold at 8½c and 870 boxes of small colored at 8½c.

UTICA, N. Y., July 16.—Cheese—Prices were 8c. 8¼c, and 8⅜c.

LITTLE FALLS, N.Y., July 16—Cheese—Prices ranged generally about 8@8⅛c, with some small at 7¾c.

BALTIMORE, Md., July 24—Butter—Market quiet; creamery separator extra, 20c; extra firsts, 18@19c; creamery first, 17@18c; creamery imitation extra, 15@16c; ladle extra, 14@15c; Western store packed, 11½@12½c.

Eggs—Market quiet; strictly fresh stock, 11@11½c.

PHILADELPHIA, Pa,, July 24—Butter—Solid packed separator creamery extra, 18½@19c; creamery firsts, 18c; seconds, 16@17c; imitation extra, 16c; firsts, 15c; seconds, 13c; ladle packed extra, 14@14½c; firsts, 13½c; seconds, 13c; print butter creamery extra, 21c; firsts, 20c; seconds, 18@19c.

Eggs—Pennsylvania and near-by, 13½@14c; Western, 13½@14c; Southwestern, 13c; Southern, 10@11c; butter firm; eggs firm.

ST. LOUIS, Mo., July 24—Butter—Steady; Creamery, 15@18½c; dairy, 12@15c.

KANSAS CITY, Mo., July 24.—Butter—Creamery 14½@16½c; dairy 14c.

Eggs—Fresh 9c.

DETROIT, Mich., July 24.—Butter—Creamery extra 19c; firsts 18c; fancy dairy 15c.

Eggs—Weak, recandled 13c.

NEW ORLEANS, La., July 24.—Butter—Market dull 18½@19c.

NEWARK, N. J., July 24.—Butter—Market quiet; 18c for fancy creamery. Receipts liberal.

Latest quotation for fancy creamery: Buffalo 19c; St. Paul 17c: Minneapolis 16½@17c.

NEW YORK MARKET.

NEW YORK, July 22.—Butter—Receipts for the week were 54,016 packages; exports for the week 4,591 packages. The position at the close of the week's trading is about the same as reported in our last; receipts continue heavy; quality of many of the best creameries is showing serious hot weather defects, and under inspection grade only as firsts and seconds. Extra creameries are still quoted and sell at 18 cents, while all other grades are freely offered at 16c and 17c. Exporters continue to buy freely, and we note sales of several thousand tubs fine creamery for this account at 17c, and long lines of fair to good ones at 15@16c. Fine June ladle butter is not offering, but sales are reported of several lots current make for export at 13½@14c. We quote—Creamery, extra 18c; medium 16½@17c; poor 15@16c; dairy extra 16½@17c; medium 15@16c; poor 13@14c; ladle, extra 14c; medium 13@13½c.

Cheese—Receipts for the week 33,006 boxes: exports for the week 13,674 boxes. We note a good, active demand from all quarters, and stocks well cleaned up at the close at an advance of fully ¼c per pound over last week's rate. Large and small cheese selling at the same prices. We quote: Full Cream, extra 9c; medium 8@8½c; poor 6@7½c; Part Skimmed, extra 8@8¼c; medium 7@7½c; poor 5@6c.

Eggs.—Receipts for the week 53,628 cases. Market is in the dumps and prices lower and weak at the close. We quote: N. Y. and Penna. strictly fresh laid, per doz, 15@15½c; western and northern, best marks 14@15c; other sections, good to fine 12½@13½c DAVID W. LEWIS & Co.

Nos. 177 & Chambers St., N. Y.

BALTIMORE MARKET.

BALTIMORE, Md., July 20—Butter—There has been quite a bit of seasonable business done this week in separator creameries, of which the receipts have been fairly liberal, particularly from the blue ribbon districts; but it is needless to add that many of the reputable brands have fallen by the wayside, so to speak, in quality, the weather proving too much of a burden for the poor cows to bear. Some of this activity has grown out of the increased demand to supply summer resorts dependent upon this and nearby markets, which latter, in turn, look to Baltimore for a supply, particularly at this time, when the short transits must be made by express to insure carriage in good condition, and Baltimore commands one end of each short transit. With respect to the prices for the under grades it may be said that they have not been altogether encouraging to the shippers; but they cannot be charged against the receivers, because they have done everything possible to get first-rate prices for second-rate goods, with the invariable results. Gathered cream makes have shown a decided decrease in quantity, but have graded relatively better than the separators, and have been sold generally on arrival. This market is very much in need of creameries in thirty pound tins or tubs and the trade that call for this size tub are not so particular as to grade of the contents. Rather an increased demand from out of town and nearby traders for prints and blocks. Store-packed receipts light; demand continues good.

Creamery separator, extras, per pound, 19c; firsts, 18c; seconds, 17c; gathered cream, extras, 17@18c; firsts, 17c; seconds, 16c; Ohio, extras, 17@18c; firsts, 17c; seconds, 16; Ohio store-packed, extras, 12½@13c; firsts, 12c; W. Va., store-packed extras, 12½@13c; firsts, 12c; creamery blocks (2 lbs.), extras, 21; firsts, 20c; seconds, 19c; prints, (½ lb.), extras, 21c; firsts, 20c; seconds, 19c; Md., Va. and Penna. prints, extras, 19c; firsts, 18c; seconds, 16@17c.

Cheese—The receipts of cheese are ample. Trade fair for season. Market firm.

N. Y. State Cheddars, fine, 8¾@9c; choice, 8½c; fair, 8@8¼c; Flats, fine, 9@9¼c; choice, 8½@8¾c; fair, 8¼c; small, fine, 9¼c; choice, 9c; fair, 8½c. Ohio Flats, fine, 8½@8¾c; choice, 8@8¼c; fair, 7½@8c; picnic, fine, 9@9¼c; choice, 8½@8¾c; fair, 8¼@8½c. Swiss cheese, fine, 13½@14c; choice, 12@13c; fair, 11c.

Eggs—The market on strictly fresh eggs is some steadier than it has been and for this kind there is a good demand at 10p value, but stock showing the effects of the late hot spell are hard to sell, even at reduced prices. The trade in general want, and will take nothing but first-class eggs at 11½c. There is still some accumulation of off grade stock. Do not ship any eggs of doubtful quality, as they do not improve by age. Oh, no. G. M. LAMB & BRO.

FOKEIGN MARKET.

BOSTON, July 22—Cable advices of this date from the principal markets of Great Britain to Geo. A. Cochrane give butter markets as steady with a further slight increase in values on some grades. Danish remains at 21@22c; Irish 19@20c, but the most active demand is in Canadians, which in consequence of their good landing condition and the weather being extremely warm, they are in great favor with buyers, and some marks have sold this week at 20c, with average lots selling at 19@19½c. There is still a good inquiry for ladles at 14@15c, but values in America prevent free business. Imitations have sold at 16@16½c, and some exceptionally fine parcels have brought 17c. The weather has been excessively hot all over Europe. The pastures however are not injured as yet.

Cheese markets are firm, and the large consumptive demand keeps arrivals well cleared up. Finest American and Canadian are selling at 9¼@9¾c, with white still commanding a slight premium over colored.

MANCHESTER MARKET, ENGLAND.

MANCHESTER, July 8—None of the butter markets this week, evinced any feeling of liveliness, but, in fact, quite the opposite. At Leith the rapid advance curtailed sales; another report says, market at a standstill. Newcastle received less butter, and was dull, with a good proportion left unsold. London was quiet at prices that did not pay shippers, and Manchester operations were conducted cautiously, with buyers endeavoring to evade the last advance. The limited supply of choicest, however, supported prices, and rendered clearance of this class easy. Arrivals were 4,734 Danish and Swedish, 548 Finnish, which, as compared with the same date last year, show the very considerable decrease of 1,774 Danish and 475 Finnish, most of which has been absorbed by the increased f. o. b. trade, importers being obliged, by the short make, to secure their butter in advance of the landed markets. Thus the present high rates f. o. b. have been possible, and the recent Danish official advances justified from their point of view. The official top quotation is unchanged. Top is eleven kroner higher than last year, and stands higher now than any year since 1893, that phenomenal season of weather forecasts upset, great drought, burnt up pastures, water famine, and small butter make. Since our last report, refreshing rains have fallen over most of Scandinavia and fear of drouths has ceased. Markets there are quieter, speculative disposition killed, and a small reaction thought not impossible. Hamburg is firmer and dearer, Irish Centrifugal Creameries are more plentiful and easier. Cork market rates on the week, about 1c lower all around. Quality very fine. Best quality Canadians are now much in evidence. The leading United States markets show no change in values, but all have lost a little of their activity. Speculators are not so sanguine of higher prices, and the make is certainly increasing. Shipments to Great Britain inconsiderable. Scandinavian shipments at sea and Finnish arrivals 20,814 casks, 134 more. Margarines and mixtures in improved demand. Arrivals of margarine, via Hull, 10,517 packages, and via Gimsbym 5,197 packages. DOWDALL BROS.

165,000 Cream Separators.

Follow the crowd and you are usually in safe company. Do as the great majority do and you take few chances. Practical experience may be always depended upon to separate the wheat from the chaff in everything.

This is naturally as true of cream separators as of anything else. The De Laval Machines were first in practical utility. 1899 is the seventeenth year of their commercial use. Throughout this period the De Laval makers have been in the van of every stage of improvement, leading step by step to the perfected "Alpha" disc machine of to-day. The De Laval machines have meanwhile been introduced into every part of the world where dairying is practiced. They have revolutionized the dairying of the world and have been the "keystone" in its modern advancement.

They are as much in the van to-day as in 1883. The "Alpha" disc process of to-day is as much superior in practical utility to other methods of cream separation as was the De Laval machine of 1883 to other creaming methods then in use.

165,000 is the sale record of the De Laval machines. This is probably ten times the number of all the imitating and would-be competing centrifugal cream separators together ever sold. The 1899 sale of De Laval machines has thus far been considerably greater than in any preceding year.

The reasons for De Laval supremacy are known to all those who understand the principles of centrifugal separation. A De Laval catalogue explaining and illustrating separator facts and differences will make it plain to those who do not. Such a catalogue may be had for the asking.

BRANCH OFFICES: 1102 Arch Street, PHILADELPHIA.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

For Sale—Herd of ten high grade Jerseys—made over 300 pounds per cow last year, half being heifers. Also five yearlings sure to make 300 pound cows. Also separator. F. M. SWIFT, Olivet, Mich.

For Sale—Creamery located in good dairy country. Three railroads and express companies. Market convenient. Address "CREAMERY," Lowellville, Ohio. 21-4

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada. 32-52

For Sale—4 Reg. Guernsey calves, 2 heifers, 1 bull. Tuberculin tested. C. H. REEVES, Salem, N. J. 23 2

Wanted—A competent man to operate and manage a 30 cow dairy, selling milk in city. Permanent employment. Jerseys. Address, J. H. BOSARD, Grand Forks, N. D.

For Sale—Fine young Guernsey bull, age 13 months. A Guernsey cow, fresh, gives good mess, but 3 teats, cheap. 4 Cooley cans, new, never used, $1.00 each. H. MOOREHOUSE, Cor. Wentworth Ave. and 19th St., Chicago, Ill.

Wanted—About Dec. 1st, two first-class single men to work on dairy farm. Must be of good habits. Permanent employment to right parties. A. L. FITCH, Westmoreland, N. Y. 24-2

Excursion Tickets to the Great American Exposition, to be held at Omaha, Neb., until October 31, 1899. Via the North-Western Line, will be sold at reduced rates. from certain stations on specified dates. For rates, dates of sale and limits of tickets apply to agents Chicago & North-Western Railway. 22-sp

Exceptionally Low Rates to Pittsburg, Pa. via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations. July 31 and August 1 (but not for trains arriving Chicago before August 1), limited to August 31, 1899 inclusive, on account of Annual Y. P. C. U., United Presbyterian Church. Apply to agents Chicago & North-Western R'y.

Excursion Tickets to Lake Mills, via the North-Western Line, will be sold at reduced rates from certain stations in Wisconsin, August 1, limited to August 2, inclusive, on account of Emancipation Barbecue Apply to agents Chicago & North-Western R'y.

Excursion Tickets to Mayville, Wis., via the North-Western Line, will be sold at reduced rates from stations in Wisconsin, August 4, 5 and 6, limited to August 8, inclusive, on account of Biennial State Turnfest. Apply to agents Chicago & Northwestern Railway.

Reduced Rates to Rock River Assembly, To be held at Dixon, Ill., July 25 to Aug. 8, will be in effect via North-Western Line from stations within 200-mile radius. For rates and dates of sate, etc., on certificate and excursion plans, apply to agents Chicago & North-Western Railway.

Comments and Queries from Robinswood Farm.

Adjustment of Cows to Environment.—Concentrated Foods Unprofitable Under Present Prices.—What to Grow to Balance the Ration.—What Cows to Keep to Consume Unbalanced Rations.

ED. HOARD'S DAIRYMAN:—I am in a position to answer some of the queries I have made in previous issues of the DAIRYMAN as the result of a somewhat expensive experience. I now see that crossing breeds is a very uncertain proceeding as to results. I believe that that much-to-be-desired-all-round-cow can be evolved; but life is too short for me to do anything at it. I would prefer taking one of the established breeds, and work it over into harmony with the conditions of our local environment. That has got to be done before the Gilmanton region becomes the great dairy region for which it is naturally adapted.

No one of the established breeds entirely fills the requirements. If the Devons had been carefully bred and handled for milk and purity in this region, for the last fifty years, they would be the most suitable for our extensive and not luxuriant hill pastures. But Devons are not fashionable now, and it would be too difficult to secure the right blood when needed. Holsteins I rule out; they would use up too much food in creating vitality to move themselves over our pastures. They are too big for the feed of the district, and too used to high feed.

The beef breeds are not for our country of difficult culture and impoverished soils. The middle West can enjoy their impoverishing effect for a time, now. The Ayrshires would do pretty well for us, if we could get them, especially for the milk farmers on the periphery of our hill district. But I don't see but that we have got to take Jerseys or Guernseys and acclimate and evolve them, if we are to continue to make butter making our specialty. The breeder, of course, would want the pure bloods, but the dairyman pure and simple, I judge, should use the pure blood, high pedigree bull, and grade up his herd by degrees, starting with cows that are used to the conditions of the district.

One thing is very evident, and that is, the Gilmanton farmer cannot afford to feed his cows high enough to secure the greatest amount of butter that is capable of being produced by his cows under a thoroughly balanced ration, and a liberal supply of concentrated nutrients. I gave it a fair trial last winter, both as to quality and quantity of food. The product of the herd in milk, both as to quantity and quality, was not excelled by any other herd supplying Gilmanton creamery, yet on every dollar's worth of concentrates bought and fed to the cows, I believe I lost at least fifty cents, even allowing a fair valuation for the feed as fertilizers.

I find on inquiry, that this has been the general experience of all the farmers in our region who have tried the experiment. I imagine that many thousands of butter farmers throughout the country are taking good money out of their own pockets and putting it into the pockets of the grain dealers, the railroad people, the mill men and butter consumers, by buying concentrates for cows at the present price of butter.

So far as I can roughly judge, with butter at present prices, cow feeds now sell at about double what they are worth for butter making purposes. Yet, with labor at present rates we can, in this region, buy digestible nutrients much cheaper than we can afford to grow them. If that is so, how much wages can a man make growing cow feeds and feeding them to cows? At first sight, it appears as if there was not much of a chance for the butter farmer. But with further thoughts we realize that the direct profit from butter is not, or should not be, the main or entire source of profit for the farmer. The main source of profit in the cow is that she is the enricher of the soil and is a means to the securing of many products that can be turned into cash. I imagine that many farmers too often forget that farming is a profession where money is made by savings in numerous channels, not excluding the great saving of being able to supply the family home market.

Farming is by no means the least profitable of professions, because the farmer handles little ready money. There are other profits of life besides the possession of the currency of the land. Nevertheless, the farmer, like everyone else, has got to get up and hustle or he will find himself left way behind in life's procession. The great problem that now faces the Gilmanton butter farmer is, what shall he grow to feed his cows with. He certainly can not afford to buy anything in the way of cow feeds under present prices. Of course the corn crop stands first, and the farmers generally see that, and are increasing their area of corn fodder every year. Then oat hay and clover hay are all right, though clover hay is an uncertain crop with us. Furthermore, the various grasses do better with us than any other cow feed.

A consideration of these facts shows that with these crops alone, there is not only a lack of concentrates, but also a lack of protein in the possible ration that can be compounded from these products. The concentrates are impractical so far as purchase is concerned, and largely so, so far as home production is concerned. Hence we must resign ourselves to a lesser yearly product of butter from each cow, and make it up by feeding more rough foods to a greater number of cows, and furnishing more stable and storage room.

But how about balancing the ration better? Would it not pay us to grow soja beans and field peas for this purpose? Will early cut crimson clover be all right for the cows? How about fall sown sand-vetch for this purpose? Another question kindly answer: Which is the best cow for a butter farmer who cannot afford to feed a perfectly balanced ration, one having a due proportion of concentrates; a cow whose ancestry has been brought up on rations of this defective character, or one whose milking tendencies have been fostered and built up by a perfectly balanced ration and a full supply of concentrates in itself and its ancestors?

Of course we rule out the mature cow thus fed and bred. She would, after years of high feeding, surely do poorly on a decreased nutritive supply. Would it not pay best to take the calf with the all milk tendency, and continually breed from bulls with such inbred tendencies, rather than to take blood whose tendency to bodily fat and growth must necessarily have been fastened by an excess of hydrocarbons in its food in proportion to the proteins. I suppose that all deep milkers would eventually become dual purpose cows if continually fed on a corn and hay diet solely; though careful selection of breeders and persistent milking would prevent the breed from becoming an all beef one.

Will Mr. Fred Zimmerman kindly state the reasons for his belief that he does not want to shrink the tissues by cold application, in local inflammations of the udder? Temperatures both above and below the normal will reduce nervous irritability in inflammations, and prove soothing; but hot applications still further paralyze already distended blood vessels in inflammations and powerfully promote the formation of pus, a desirable thing in extreme cases; but to be avoided, if possible, whenever inflammation can otherwise be practically repressed and brought to an end.

J. M. W. KITCHEN, M. D.

New Hampshire.

Mistakes on the Dairy Farm.

(Read at the Meeting of the Pennsylvania Dairy Association, by FRED LASEUR.)

The first great mistake is want of preparation. Few would embark in any other profession—for farming has become a profession—without some preparatory work. Few farmers have any adequate idea of the capabilities of their farms. The limit of an acre in production is unknown. The limit of the dairy cow seems also to be unknown. We read of a dairy average of 476 pounds of butter per cow per year. Andrew Baker's herd reports about 435 pounds per cow. All dairymen are not liars, and we are compelled to believe some of these statements of yield. It requires skill and perseverance to obtain such results, and they seem far off to me, with my 270 to 300 pounds average per year.

The dairy cow is a conundrum to me. I have never been able to guess her. I have thought at times that I knew something about her, but I have about made up my mind that I don't. It is all very well for learned men to say that "bossy" never makes any mistake, that she is just like a machine and will do for you what you do for her, but if they will take her under all kinds of conditions, they will find that she does some very strange things. I have fed cows under quite varied conditions, and I find that you must have the right kind of cows to start with. They have got to have the capacity. Every cow has her limit, and when you reach it you have got to stop. My cows seem to stop before they reach it. I believe a great many make a mistake in choosing their cows. We must know what we want a cow to do. If we want butter, we must have the dairy cow; if we want beef, we must have the beef cow, and if we want both beef and butter, we have got to have something besides Jerseys. I believe in the special purpose cow for the special purpose farmer, but for the average cow keeper—and most farmers are cow keepers and not dairymen, for real dairymen are scarce—the general purpose cow will do about as well as any.

I have spoken of some large butter yields; now I will mention a small one, and see if you will believe the statement. I have a neighbor who draws milk for a cow-keeper, who keeps an average of about sixteen cows, and gets from the creamery, in eight months, $256. Those cows are not mortgage-lifters, nor the man either. Skill is what counts. Did you ever think that the more skill you sell the more you have to sell?

One great mistake many cow-keepers make (notice I did not say dairymen) is in not building up their soil, for there is where nearly all life is nourished, both animal and vegetable, either directly or indirectly. Robbing the soil of its fertility is a serious thing. It takes too many acres of land to keep a cow in our country—all the way from five to ten acres. I believe we can keep a cow cheaper upon one acre than upon ten. If it took ten acres for me to feed a cow, I could only keep four cows, for I have only about forty acres, and I am only farming twenty-three acres. As soon as I can get so I can farm that I expect to live without work.

We are keeping, this winter, twenty-seven head of stock—sixteen cows, two horses, seven yearlings and two calves. The rough feed they are eating grew upon less than fifteen acres. The grain ration which we feed to our cows costs us at the rate of three and one-half cents per pound of butter, while our cows are not doing anything like what they ought to do. We think we have solved one problem—how to run a dairy and not buy so much grain. We have done it with clover hay and the silo.

The saving of manure is also a very important factor in dairy farming. We are told by scientific men that the nitrogen in the liquid manure nearly all escapes in eight or nine days if it is not drawn to the field. Our manure goes out every day except Sunday. We hope that in a year or two we can cover our farm every year with manure, and with good tillage we think we can commence to produce crops that will pay. We expect our farm to carry twenty-five cows, in two or three years. I do not know how intensive we can farm and make it profitable, but I know I am far from the limit yet. Which is worth the more, twenty-five acres that will keep twenty-five cows, or 100 acres that will keep twenty-five cows? I believe we can produce the feed on twenty-five acres cheaper than we can upon 100, and the cost of production is a very important item in the dairy.

I would like to know what it cost these record breaking herds to produce butter. If they cannot produce it any cheaper than we can with our 300-pound cows, they are not so far ahead of us after all. But I believe, other things being equal, the more butter a herd of cows makes the cheaper it can be produced. What do you suppose it costs to produce a pound of butter from those sixteen dollar cows? I should say about 50 cents per pound. If all farmers knew what it cost them to produce a pound of butter, some of them would change their methods or go out of the butter business. We cannot control the market, but we can, by using skill and intelligence, lessen the cost of production to quite an extent.

We must use the oars we have to row the boat of life; make the best of what we have; take good care of what we have, and improve our methods. We have not all got 400 and 500-pound herds, but let us do the best we can with the ones we have and keep constantly working for improvement and betterment of our dairies. We must test these matters with our own thermometer, measure them all with our own yard stick, and if we find we are not correct, change to correct methods. We must read more, and study more, learn more; read to learn; learn to know; know to act; and when we get that 400 and 500-pound herd we will be in the swim with the rest of the big dairymen.

The World Cannot Show Its Equal

In STYLE, CONVENIENCE and DURABILITY.

Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairyman at bed rock prices. For description and price address,

Separators and Their Management.

[A Paper read by MARK SPRAGUE at the Cheese and Butter Makers' Convention.]

One of the common properties of matter, is its indisposition to move. This is manifested in a body by the opposition it offers to any change in its motion. Any such change must be effected by force. In all the older methods, creaming was effected through the influence of gravity, which is, practically, always the same. It is quite different, however, creaming milk with a separator, for in this method the aim is to separate the fat by centrifugal action, which is much more powerful than the force of gravity.

The natural force of gravity, which is universal, and at all times available, and which was exclusively used in cream raising, acts with uniformity, and requires a certain time in which to obtain the best possible results, but even under the most favorable conditions it fails to obtain complete separation of the fat with varied or mixed milk. More perfect separation, and a shortening of the time necessary for creaming milk, can only be effected by the application of a force which will impart to the fat globules a motion far exceeding that given by gravity.

This force is centrifugal force, and it is from this the machines for creaming milk are named centrifugal separators. It can be applied in such a manner that its power exceeds that of gravity more than a thousand times. It is only necessary to subject the milk to a rapid rotary motion in a suitable vessel to produce this force. A machine having suitable arrangements so that when at work, a continuous stream of milk can be admitted, and give out in return separated cream and skim milk, is termed a separator. That portion of a separator which is to hold the milk, and is called the bowl, forms the essential part of every separator, and revolves around a vertical axis, and must always be a rotary body, of necessity made of good material, to withstand the lateral pressue to which it is subjected.

The milk when put into the separator bowl, may be said to undergo much the same conditions and action, as when it stands quietly at rest in a pan or can. Just as milk when it is poured in a steady stream into a can, finds at once, the lowest part of the can, which is the bottom, spreads itself over the bottom in a horizontal layer, and gradually fills the vessel from bottom to top, so does milk allowed to flow into a separator bowl when at speed, find its way with lightning rapidity to the most distant part of the bowl, spreading out into a cylindrical surface until the bowl is gradually filled from the outside to the inside. Just as milk standing in a milk pan at rest, exercises pressure on

the bottom and sides of the pan, due to the force of gravity. So precisely milk, in a separator bowl in motion, exercises a pressure on the sides of the bowl, which is due to centrifugal force, and is in proportion to the speed and diameter of the bowl. As the fat globules move upward in the pan, in a direction opposite to that in which the gravity acts, so the fat gobules in a separator bowl, filled with milk, and in motion, travel in a direction opposite to that of centrifugal force, or inward or from the outside to the inside of the bowl.

Separator bowls are so constructed that the milk flowing in is delivered into them near the circumference, or at a point outside of the perpendicular layer of cream, to avoid the milk passing with force through these layers and displacing them and thus interfering with perfect separation. The outflow of cream and skim milk from a separator bowl takes place with considerable force or energy and is proportionately equal to the speed at which the bowl is driven and the distance from the axis at which it delivers. In order to reduce the force as much as possible to avoid whipping the cream, the exit for the outflow of cream is placed as near the axis as can be. The outflow of cream and milk together equal the amount of milk which flows into the bowl in a given time. The proportion of the weight of cream to skim milk is determined by the rapidity with which the milk flows into the bowl, and in all separators the thickness of cream can be regulated at will by this means when the separator is at speed. For the winter season, in almost all separators, there are arrangements whereby it is possible to regulate the quantity of cream with a uniform inflow of milk and to adjust the separator to skim milk successfully, of different percentages of fat and maintain a normal capacity. The three main points to be observed in operating a separator are—feed, speed, and temperature of the milk.

The greater the feed of milk entering a separator, the shorter the time it can remain in the bowl exposed to the centrifugal force, and if the feeding be carried beyond a certain limit there must be more or less imperfect separation of the fat from the milk. This can be determined by the flow of cream; as has been stated the quantity entering the bowl equals the cream and skim milk from it. And the thickness of cream is regulated by feed, consequently if the cream be too thin, it is an evidence of its not having been retained in the bowl sufficient time to complete the separation. The feed should be even and regular, as nearly as can be.

There is to every separator a safe and proper speed at which the best results are obtained. This is usually stamped on the bowl, and is as high a rate as the manufacturer feels secure in recommending, and this should never be exceeded to any great extent, as it might result in injury to the separator or the operator, or perhaps both. It is essential, however, that the desired speed be maintained regularly and evenly while separating, remembering that any cause that might demand higher speed can be met by reducing the feed.

Temperature of the milk to be separated is important. The mode and time of tempering before it passes into the separator are all important facts in successful and exhaustive skimming. Higher temperatures increase the difference in specific gravity between the fats and other parts of the milk, provided time is allowed for expansion of the fat to take place before it passes into the separator, which is about three to five minutes. It also reduces the viscosity of milk, making it more fluid, when it will flow faster and offer less resistance to the transit of the fat through it toward the centre of the bowl, thereby increasing the capacity and effectiveness of any separator.

Large amounts of milk should not be heated to a temperature suitable for separation in any case, as the formation of lactic acid, and the coagulation of the casein go on so rapidly that the milk is in a condition to leave a residue which adheres to the sides of the bowl, clogging the skim milk outlet and making it necessary to stop oftener than would have been the case, if smaller amounts were heated as required by the best separator.

In my opinion there is no such thing as one separator containing points superior in every respect to all others; and, again, a separator for one may not be suitable for another. It is not in accordance with the eternal fitness of things and the patent laws, that it should. The value of a separator is determined chiefly, though not exclusively, by its capacity for work. This is best measured by the quantity of milk which it can be made to cream in an economical manner, at a fixed cost.

It is also very questionable whether circumstances may not exist in which, where very slight differences in their capacities exist, the less capable of two separators may not be preferable—since it may possess certain advantages which appear to be of little importance, yet have a material value in the circumstances in which they are used.

FERTILITY ELEMENTS IN FARM PRODUCE.

Its Effect on the Productiveness of the Farm.

As the DAIRYMAN has repeatedly stated, one of the very important considerations in dairying is its beneficial effect on the crop producing power of the farm. Mr. C. M. Macfie, of Appin, Ontario, contributes the following, based on his experience, to the Farm Institute Report of that Province:

"In connection with dairying, the by-products are an important factor, as the utilization of them are becoming more and more an important factor in every line of manufacturing.

"The skim milk and buttermilk from one ton of butter has, at 20 cents per cwt., a feeding value for hogs of about $80, if fed in conjuction with meal. The whey from a ton of cheese has a feeding value of about $18, when sweet; when sour, a little less. It must be remembered too, that of the organic matter in foods, there are certain quantities of constituents which do not digest, and these assist in giving manurial value to the foods fed.

"The foods of the successful dairyman are usually corn ensilage, clover hay, oat straw, oat and pea meal, bran, and sometimes oil cake. According to an analysis by one of the American experiment stations, these have a manurial value as follows:

	Per ton.
Corn ensilage	$ 3.00
Clover hay	10.00
Oat straw and chaff	2.00
Oat meal	10.00
Pea meal	12.00
Bran	13.00
Oil cake	24.00

"We will suppose a man feeds ten cows for six months of the year, a daily ration consisting of six pounds of clover hay, 40 pounds ensilage, six pounds of oat straw, two pounds oat meal, two pounds pea meal, five pounds bran. During the six months he would feed:

5 2-5 tons of clover hay, adding fertility to the farm	$ 54.00
36 tons ensilage, adding fertility to the farm	108.00
5 2-5 tons oat straw, adding fertility to the farm	11.00
1 4-5 tons oats, adding fertility to the farm	18.00
1 4-5 tons peas, adding fertility to the farm	21.00
4½ tons bran, adding fertility to the farm	58.00
Total fertility, value added to soil (if manure is saved without loss)	$270.00

"If one ton of oil cake were added to the above quantity, it would improve the value of the food ration, and add to the fertility of the soil still further.

"Dairying also assists in the increase of soil fertility by enabling the farmer to utilize all the crops grown on the farm. The crop of a good, one-hundred acre farm in Eastern Ontario, besides the wheat crop, at present market prices, would be about as follows:

Hay, 15 acres	30	tons
Oats, 15 acres	600	bushels
Barley, 7½ acres	225	"
Corn, 10 acres	400	"
Peas, 7½ acres	150	"

"Suppose he sells one-half his hay crop, and all his grain, he receives for all about $520, at present prices. The value of the fertility of the crop sold is about $325. The manurial value of the fodder fed, after selling the produce, is about $300, while the manurial value of all his crop, if fed on the farm, would be $650.

* * * * *

"The good dairyman, too, is always interested in producing the best article possible. He takes the best care of his milk, and is interested in its manufacture into cheese and butter of the best quality, so that his produce always finds a ready sale."

WISCONSIN'S PURE FOOD LAW.

Dairy and Food Commissioner Adams, of Wisconsin, issued a circular letter last week to dealers in food products, calling attention to the statutes and transmitting various rulings made by him in reference thereto. Those parts of the letter of special interest to dairymen and consumers of dairy products are given below. That they are eminently fair to both producer and consumer, and in the interests of good health and good morals, is so evident that only those trained in the art of not seeing what they do not want to see, can find anything to complain of.

Producers and dealers in milk and cream are specially warned against the use of preservatives.

The preparations for keeping milk and cream sweet, that are widely advertised in this state as being harmless, have been condemned by leading authorities, both in this country and in Europe, as being prejudicial to the public health. Their use is prohibited by a plain statute which fixes the minimum penalty of $25 for its violation. Preservatives are used to avoid the effects of careless and unclean methods.

Milk and cream will remain sweet without the use of poisonous drugs, long enough for sale and consumption, if produced from clean cows, in clean barns, by clean men using clean utensils.

The health of invalids and of children is of more importance to the state than the prosperity of manufacturers and dealers in the makeshifts of uncleanliness.

Oleomargarine can be manufactured and sold under its own name and color when properly labeled. Each tub, package and parcel shall be marked by a placard bearing the word "oleomargarine" printed in plain uncondensed gothic letters not less than one inch long, and such placard shall contain no other words thereon.

All stores and places of business from which oleomargarine shall be sold, must have conspicuously posted a placard, to be approved by the dairy and food commissioner, containing the words, printed in letters not less than four inches in length, "OLEOMARGARINE SOLD HERE."

Oleomargarine colored in imitation of butter cannot be sold.

It is unlawful for hotel, restaurant and boarding house keepers to furnish their guests with butter substitutes without notifying such guests that the substitutes so furnished are not butter.

A bill of fare furnished guests containing a statement that oleomargarine is used will be deemed a sufficient notice.

Renovated butter, which is butter of inferior quality, melted, regranulated, churned with milk and worked over into the appearance of fresh creamery butter, must be branded "renovated butter" upon each tub, package and parcel.

No imitation butter or cheese can be used in any of the charitable or penal institutions of this state.

CHEESE—The Dairy and Food Commissioner is authorized to issue to the owner or manager of each factory making full cream cheese a stencil containing the number of the factory and the state brand, "WISCONSIN FULL CREAM CHEESE." The manufacture and sale of filled cheese is prohibited.

The manufacture and sale of skimmed cheese is prohibited, except when such cheese is made ten inches in diameter and nine inches in height.

MILK—All milk offered for sale or sold must be from healthy cows, of clean and wholesome character, unadulterated, free from preservatives, and must not contain less than three per cent of butter fat.

Feeding Notes from Michigan.

Broom Corn Millet.—Effect of Sorghum on Bull.—Growing Sorghum.

ED. HOARD'S DAIRYMAN:—I have raised broom corn millet and fed it to cows. It is so called because its head is like that of broom corn. It is also called hog millet, and sometimes, incorrectly, German millet. It is shorter and coarser than the other millets, and matures two weeks earlier than common millet. It does not yield as much forage as the other varieties, but yields very heavily of grain. The seeds are much larger than those of the other varieties, being nearly as large as those of broom corn. When ground they form a concentrated grain, somewhat similar to corn meal but richer in protein and fat. The plant will thrive on poorer and drier soil than the other millets. If a sufficient growth is secured just before the seed forms, this is the best time to cut it, but unless the land is rich it is apt to be short at this time and then it is better to cut it just as it begins to turn yellow and thresh and grind the grain.

If fed to cows without threshing the grain is utterly wasted, as the manure will be full of it, and if fed in warm weather, the seed will grow so that the droppings will be covered with the young sprouts.

The threshed straw makes good hay for cows. It threshes very easily and it does not require very much labor to pound it out with a flail as it is used. It would probably make the same quality of silage as the other millets.

I have raised and fed sorghum for the past three years with good results, but have not fed much second growth until several feet high, except after it was cured.

As the ratio of sorghum is wide, it answers well to supplement short pasture with its narrow ratio, but is not suitable for a complete ration.

Last year we fed a young bull upon sorghum and chop feed for some time, and when we came to use him we found him utterly sterile, and I had to sell him for beef.

About that time the effect of silage upon the potency of bulls was discussed in your paper, and I concluded that my bull had had too much molasses.

When sorghum is sowed on well manured land for forage it should be very thick. When thinly sown the sugar content of the large stalks throws it entirely out of balance for cow feed.

I get the best results by using the drill set for sowing fodder corn—one peck to the acre, or set at six pecks with the rows forty-two inches apart. As the sorghum seed is so much smaller than corn, this gives a dense growth of small, but tall, stalks with a large amount of foliage and seed, and there is never any of it wasted. W. H.

Howell, Mich.

Washing Dairy Utensils.

ED. HOARD'S DAIRYAMN:—I want to say a word here in regard to washing milk pails and utensils. I may be running into hornets nests but I can't help it. My impression is that there are too many dish cloths used and not enough *boiling* water. I know from experience that it is hard work to keep a dish cloth sweet and clean in hot weather, and a brush that will take the place of a dish cloth, that can be bought in any place for twenty-five cents is much better for getting into seams and crevices than a cloth, and it is no trouble to keep clean. Keeping milk cans clean and bright is no easy task, but leaving them unclean means gassy and bad flavored milk and I think I can safely say that fifty per cent of the bad milk delivered at factories to-day is caused by neglect on the part of the patrons to keep their cows and dairy utensils clean. Another practice that I have noticed is stopping up leaks in milk cans with a rag. This is positively a filthy practice and should be abandoned at once. J. H. SCOTT.

Harrietsville, Ont.

Preservatives in City Milk.

A report from Fort Wayne, Indiana, states that 36 samples of milk sold by regular dealers were examined, and only one was free from chemicals used for preserving. The authorities promise to publish a list of the dealers whose milk is free from chemicals, and another giving the names of those who use them. These lists ought to be published in the daily papers, so that the public may know just what they are buying. We have always claimed that this publicity is the only way to drive adulteration frauds and humbugs out of business. Their whole trade is a counterfeit one, based on an effort to sell an inferior or poisoned article under the guise of pure and wholesome food. Publish their names in full, and show the people just what they are selling! That is the surest and quickest way to drive them out of business!—*Rural New Yorker.*

POOR pasture, heat and flies have formed a trust to lower the production of the cow that is not protected from their methods of doing business. The firm of soiling crop, dark stable, and kerosene, will do much to prevent the method of the trust from being successful, but how many dairymen are doing business with the last named firm, either singly or with all the partners together?

Many of them, we fear, are allowing the butter production of their herd to slide gradually down to the lowest point without making an earnest endeavor to remedy the evil produced by short pastures or flies.

Reformation of the Milk Trade Through Ice Milk.

ED. HOARD'S DAIRYMAN:—The question as to the supply of the large cities of this country with "ice milk", so called, has hardly yet been touched upon. And yet it is a system which already has proven an absolute success wherever it has been introduced in the proper manner.

Still it is especially in Denmark where this system has made effective headway, as established and patented over three years ago, by mechanical engineer Casse, and it is his method which now is getting the serious attention in other countries by those in different ways interested in the city milk supply, whether from a consumer's, or dealer's, or producer's standpoint.

That the opinions as yet are very much divided, as to the practicability and advisability of such a transformation of the general milk supply of cities, is a matter of course; every one is, generally, first on the lookout for his own advantage, and many producers and dealers look upon such a reform as the ruin of a well paying business, such as has been carried on by them thus far without interference or competition by those located at a farther distance.

With the introduction of "ice milk" and reduced rail road rates for such from a distance, the competition seems unlimited, and nearby producers see the great advantages they so far have enjoyed, disappearing, as whole trains of partly frozen milk of almost unlimited keeping quality, run into the city. And they are right so far, as they will surely have to get out of their old established ruts, and follow—or rather lead—the procession, or be left behind to die.

But right here is where I believe the great advantage to both producers and consumers will appear, in a pretty near future.

First of all I wish to call the attention of all producers, whether of butter, cheese or milk in its natural state, that every producer who wishes to make a real and lasting success, must first consider

THE SATISFACTION OF THE CONSUMER.

Being a producer myself, and writing here principally for producers, I wish, especially, to emphasize the importance of this point.

Too many producers of milk and dairy products consider only their own advantage (or suppose rather falsely to be doing so) and will tell you they don't care a snap as long as they get their fair price, whether the consumer is really pleased or not.

Every butter and cheese maker knows this only too well, having found that a majority of patrons only care for having their milk received at the factory and paid for, no matter how much trouble they may cause the butter maker in turning out a first-class product from inferior milk.

Very few butter and cheese makers care to take any extra trouble or to work extra time to improve their product, as long as the commission man does not kick too bad, and as long as the proprietors of the factory seem satisfied and do not threaten to make a change. It is only when the danger of competition becomes too imminent that these different parties begin to open their eyes and acknowledge the evil of their ways, and start to make inquiries how to improve things. And then it is often too late; it is far easier to keep at the top by constantly having the eyes open for every improvement in your business, as shown by others in other places, and by adapting yourself to the natural progress of things, and keep on improving yourself.

When this writer, some seven or eight years ago, began urging the great benefits which were derived by pasteurizing generally, and showed, by practical work, how much advantage could be gained by it, especially for city milk and cream supply, then most people considered it a fad, which soon would disappear like so much other nonsense.

But how is it now? While at that time very few even understood what pasteurization meant, far less had any idea what it might accomplish for them; to-day we can hardly take any dairy publication in hand without finding several items on that subject, and nobody now will deny that pasteurization even in this country is making steady headway, both for milk supply and for butter making.

Will the readers of this believe me when I now claim that the introduction of Casse's system for ice milk supply to cities from a far distance, is coming as surely as pasteurization and pure cultures for butter making? You will see it in a few years hence, provided some still better invention should not show up very soon. In these days we never know what we may look for next, and the very unexpected is constantly taking place. But after these preliminary remarks I shall return to the main question.

ICE MILK FOR THE CITIES.

It was in Copenhagen, Denmark, where Casse's system was first introduced and with such absolute success, and this is so much more to be emphasized, because no city anywhere was probably before that better supplied with good and pure milk than Copenhagen.

Keep in mind that it is in that city where Mr. Busch, of "Scandinavian Preserved Butter" fame, established his magnificent "Copenhagen Milk Supply," and caused a revolution eight or ten years ago, making it possible for the consumer of limited means to obtain the purest milk at reasonable cost.

And that grand business is in active operation to-day and having a moral effect on the whole milk trade of that city. And yet there was room at the top for something still better, and Casse's system flourishes. And not only does he supply Copenhagen with milk coming from other islands, but large quantities are shipped to England, and in spite of much opposition by local milk producers, has attained a strong foothold in that market.

Now Germany is having its eyes opened and sees the possibility of great improvement in that line of their city supply. A German mechanical engineer, Helm, has studied the system in Denmark and has now taken out patents for Germany and all European countries, and it will only be a question of time how long the local dealers' opposition will be able to detain the introduction of ice milk in Berlin and other cities. Lately Mr. Helm delivered an address before the Agricultural Society of Pommern and Stettin, and from this I shall make such extracts and draw such suggestions as seem to me to be useful and practicable in the different parts of the United States.

FROZEN MILK NOTHING NEW.

Oh, no! We butter makers only know that too well, and have had much inconvenience in that line. Still this "ice milk" question will help to dissipate the false doctrines held by so many practical buttermakers years ago, that "freezing of milk and cream made the butter bitter," etc., which I have good reason to remember, when all came down on me with a vengeance as a "know-nothing," because I contended that just as fine butter could be produced from frozen milk.

Already in 1861 thorough experiments were made in Germany, proving the far superior keeping qualities of well cooled milk. But altogether frozen milk was inconvenient to handle, and nothing really practical was accomplished in that line until Mr. Casse brought out his system by which the bulk of the milk is simply kept ice cold by the partly frozen milk floating in it; and while many now will say that it is such a simple thing to do, that anybody can do it, the fact remains that nobody else had thought of it or tried it before.

THE TASTE OF ICE MILK PERFECT.

Everyone who has had the opportunity to examine the Copenhagen enterprise has been charmed with the perfect flavor of the milk, and this fact has resulted in such an increased demand, that the present facilities for preparing the product for market have been found insufficient, as at the same time the keeping quality of the milk in Copenhagen has proven so excellent, that it could be sold as perfectly fresh milk when four weeks old.

The fact is that on account of sudden extremely cold and wet weather, once 50,000 gallons of ice milk were left on hand, which upon the change to hot weather was sold out in a few days. The ice milk furnished to Berlin (from points in Germany) providing it was properly prepared, gained the fullest confidence of the milk dealers, ice-skim milk also proving a great success; the concern furnishing it not being capable at all to fill the demand during hot weather.

UNSATISFACTORY ICE MILK.

Such has at times appeared in the German market, but the trouble has always been with the milk before being frozen, not having been carefully and properly handled, and of course having contracted the slightest acidity before freezing, even if not perceptible to the taste, would result in very rapid deterioration when reaching the creameries.

CONCLUSIONS DRAWN IN GERMANY.

First.—That the conditions as to milk production and climate are not near as favorable in Germany as in Denmark.

Second.—That larger establishments cannot count upon the supply of such perfect milk as they can in Denmark.

I am sure that these remarks apply almost exactly to most parts of the United States, and especially as to climatic difficulties, in a still higher degree; our weather and temperatures, at least east of the Rocky Moun-

Butter Bred Bull Calf, 10 MOS. OLD, a Little White.
Very handsome . . . Send For Pedigree. **$50.** J. P. BRADBURY Pomeroy, Ohio.

St. Lambert Jerseys, all ages, both sexes. Some from tested cows at low prices. W. J. HUSSEY, Mt. Pleasant, Ohio.

THE Evergreen Farm Herd of A. J. C. C. Jerseys is now headed by St. Lambert of Brodhead, whose pedigree is unequaled in the northwest. We should be pleased to have any one in want of Jerseys to write us for catalogue, stating just what is wanted. N. N. PALMER & SON, Brodhead, Wis.

Introduce Milking Jersey Stock INTO YOUR HERD
by buying one of our bull calves. Our herd of 325 has been bred for milk for 17 years. Best blood, size and constitution. Selected stock. Large English Berkshires, all ages, at their best. Write for our "little book."
FILSTON FARM, Glencoe, Md.

High-Class JERSEYS
The blood of Combination. (Sire of 25 in list) through Brown Bessie, (Champion Butter Cow at World's Fair), and Diploma 16219 sire of 48 in list including Merry Maiden. Young bulls, also cows and heifers bred to Recorder 29239—son of Brown Bessie. Printed pedigrees. State what is wanted.
H. C. TAYLOR, Orfordville, Wis.

Hood Farm Jerseys Rich blood. Inbred Tormentor Bull for sale. Dropped Feb. 6, 1899. Some white markings. Sire, Torono, full brother of Sophie Hudson, 19 lbs. 12½ oz., 11,496 lbs. 2 oz. milk testing 716 lbs. 14 oz., butter in 10 months. Dam, Nannie of Hood Farm, 14 lbs. 5½ oz. with 2d calf, by Fancy's Harry; 2d dam, Nannie Lee Morgan, by Tormentor; 3d dam, Landseer's Fancy, 29 lbs. ½ oz. in 7 days, 936 lbs. 14¾ oz. in 1 year, dam of 5 in the list. Write for price to HOOD FARM, Lowell, Mass.

GREEN PLAIN HERD
POLLED JERSEY CATTLE
Recorded stock FOR SALE. Inquiries promptly answered. W. H. FORBES, Clifton, Ohio.

Diplomas Combination 39962.
For Sale—Bulls and Heifers by him out of Fancy's Harry. Signal cows, some of them tested. Write us. J. E. TYRRELL, Marysville, O.

ONE YEARLING BULL
Out of a tested dam and TWO BULL CALVES out of large milking dams, for sale. Write for price. W. R. THOMAS, Bellmore, Ind.

PROSPECT HILL JERSEY HERD.
WISCONSIN PRIZE HERD.
Young Stock from 400 Pound Cows for sale. Come and see them. TUBERCULIN TESTED.
F. H. SCRIBNER, Rosendale, Wis.

ST. OMER HERD Sons of General Signal and double grandsons of Exile of St. L., with 50 to 62½% of his blood, in exchange for good registered cows and heifers due to calve this fall.
JOS. T. HOOPES, Bynum, Md.

Linden Lawn Farming Co., OLNEY, ILL.
Estab. '90. (*Capital Stock $100,000.00.*) Inc. '97. 640 ACRES. Breeders of Jersey and Aberdeen Angus Cattle. Poland-China and Yorkshire Hogs. Pure bred Poultry. Send for our plan of Co-operative Farming and Investments C. S. MACE, Manager.

...FOR SALE...
Pedro Blood!
A GRANDSON OF PEDRO 3187,
carrying 43¾ per cent of his blood. A handsome, thrifty fellow, 10 months old. Solid grey in color. Dam made over 400 lbs. butter with second calf. Will send pedigree and photos of sire and dam.
R. C. GREEN, Albion, Wis.

WILL SELL FOR $100
A GRAND-DAUGHTER OF PEDRO 3187, carrying also, Eurotas blood close through dam, besides plenty other butter blood. Five months old, solid color, extra udder; crated, f. o. b.
W. F. McSPARRAN, Furniss, Pa.

JERSEY AND HOLSTEIN BULLS
Five good, young bulls of the above breeds for sale at reasonable prices. Also a few good Jersey cows and heifers. Good individuals, superior breeding and heavy milking ancestry. Address
Farm Department, Iowa Agr'l College, AMES, IOWA.

Fancy Jersey Cattle.
Service Bull,
PEDRO'S HANDSOME PRINCE, NO. 42794.
The cows in this herd are of the best families of milk and butter producers. We have for sale young bulls by Pedro's Handsome prince and Exile of St. Lambert 55, No. 36073, out of tested cows. Write for prices and pedigrees.

We Have Sold
SEVERAL OF The A. J. C. C. COWS advertised March 17th (see page 92), in fact we quoted prices that made them desirable. There still remain some as well bred as those sold, which we think genuine bargains. We also have a few heifers that will be right to breed at time of turning out to grass. For cows, write for List No. 3, giving short pedigrees; for heifers, List No. 2.
WINTERGREEN HILL FARM CO., Scottsville, N. Y.

For Sale . . . BULL CALF,
Grand-son of the great Exile of St. Lambert 13657, sire of 72 tested daughters, "more than any other bull, living or dead." He is thrifty and good size; solid fawn color. His dam has a butter test of 15 lbs. 8½ oz. in seven days. He will be sold cheap.
P. J. COGSWELL, Rochester, N. Y.

Biltmore Farms' JERSEYS.
This is a working herd of 250 of the best native and imported breeding, selected for work at the pail, constitution and individuality. All Tuberculin Tested. Above the fever line, so we can ship anywhere.
SOME CHOICELY BRED
Bull Calves
out of great cows and by the best sires, for sale at Dairymen's Prices. Also large English Berkshires, imported and native bred. Apply to
GEO. F. WESTON, Supt., Biltmore, N. C.

MILLER & SIBLEYS JERSEYS.
Ida's Rioter of St. L. leads all other bulls in average for 29 tested daughters, viz.: over 20 lbs. of butter apiece in a week. All full weekly tests, by eight different owners. He weighed 1,760 lbs. His dam's record, 455½ lbs. milk, 30 lbs. 2¼ oz. butter (official test) in 7 days. FOR SALE—Grandsons and granddaughters of Ida's Rioter of St. L.; also cows in calf to his sons.
224 First Prizes and Sweepstakes at 22 State Fairs or great Expositions. Big cows, Sound cows, Heavy Milkers and Great Butter Makers. Our Adelaide of St. Lambert gave 82¾ lbs. milk in one day, 2005¼ lbs. in one month, the world's Jersey record. Many other championship records. No catalogue. Special literature sent if this paper is mentioned. No animal sold for less than $100. Lowest price for quality. Every animal tuberculin tested before sale, if desired. Also for sale, Children's Ponies and Imported Shropshire Sheep.
224
Franklin, Venango Co., Pa.

The Lone Tree Jerseys
THE largest collection of high testing cattle in the West, including home-bred and Island cows. Show and Breeding Stock always in supply. Especial attention given to furnishing foundation stock for pedigreed herds. A superb lot of young bulls and heifers now in special offer, including some sure prize winners.
Introduce Fresh Island Blood Into Your Herd.
SIRES IN SERVICE:—The prize winning IDA'S RIOTER OF ST. LAMBERT 10th, the champion CATONO KHEDIVE, the champion CZAR COOMASSIE, and IMP. GOLDEN BAR, inbred through his sire, Aristocrat, and his dam, Imp. Sandgate, to Golden Lad, the greatest bull on the Island of Jersey.
Write for what you want. Visitors always welcome. JOHN E. ROBBINS, Greensburg, Ind.

tains, being far more changeable than in any part of Europe.

But these very difficulties have compelled American creamerymen to make better headway than the Germans in one line especially, and that is the establishment of refrigerating plants in connection with the creameries. It is just the introduction of such that the German engineer is recommending, as such will be absolutely necessary for the production of ice milk. Here then we are actually a good step in advance, and every creamery supplied with a good refrigerating plant would be able, with very slight expense, to go into the ice milk business also, adapting the amount of production, according to the butter as well as the milk demand.

TUBERCLE-FREE ICE MILK.

Without following into detail the suggestions as especially adapted for Berlin by the German writer, I shall only use such as I think may be applied to our conditions.

There can be no doubt that the demand for guaranteed (that is really and truly so) tubercle-free milk and cream, as well as free from other infectious diseases, will be on a rapid increase in our cities; and any one who has common sense can readily understand that it is easier for the authorities to keep control of the work and proceedings of a limited number of large dairy farms and large manufacturing establishments, than of a larger number of smaller concerns.

And while I most assuredly have no use for "trusts", still I believe in centralization and condensation of work, as it both cheapens cost of production, as well as lessens the work of thorough inspection and examination, and this is the only kind of any use to either producer or consumer.

Now as to milk guaranteed free from tuberculosis, such may only be applied in two ways:

First.—From dairies where the cows are regularly examined and tested by tuberculosis test, only those being absolutely healthy to be kept.

Second.—From such creameries or milk-collecting stations where only good and absolutely sweet milk is received, and where such is either filtered or run through a separator for absolute purification, and then immediately pasteurized in such a manner as to destroy tubercle germs, which might be present.

In both these ways absolutely healthy milk may be secured, but under our present conditions I think that the system of pasteurization will take the lead. It will be a long time yet, I believe, before we shall be able to secure absolutely tubercle-free milk and cream from such a number of farms, that their product would cut much of a figure in the supply of our large cities.

If these soon shall be freed from impure and unhealthy milk and cream, this result must be reached by pasteurization—and pasteurized ice milk if supplied from a far distance, as I expect it soon will be. Some might here ask me, why it is that our

PASTEUR MILK LABORATORY

furnishes about four times as much raw milk as pasteurized? But this is easily explained as the medical society here has appointed their own inspection committee, which sees to it that the cows on our farm, close to the city, are kept free from disease, and by constant and regular examinations of samples from here, at the agriculture laboratory, are posted as to the purity of the milk; these safe guards being well known to the public.

It is natural with a price difference of two cents per quart the pasturized milk is only demanded for babies, and not even always for these. When the milk is collected from a number of farms this care is entirely different and pasturization becomes a necessary safe guard.

DIFFICULTIES IN PRESENT MANNER OF CITY MILK AND CREAM SUPPLY.

One of the greatest of these, both for producer and dealer, lies in the difficulty of adjusting the supply to the demand. The nearby dairymen all want to sell all the milk they can produce, and any surplus is almost a dead loss, as they seldom have proper arrangement to make a good product of the surplus.

So the dealer often is overstocked, and again if he for some occassion should desire an extra supply, it cannot be found. His loss from an unsold surplus makes it necessary for him to make a larger profit on what he sells, than what he would need to make if he was sure never to lose a gallon and always to be able to get just what he needed on the shortest notice.

This result can only be reached by the introduction of the ice milk system, such to be supplied from perfectly arranged creameries along railroad lines to the cities.

THE FIRST ICE MILK FACTORY

in this country is going to make a hit! But lookout, whoever will try to make the first attempt, that you are not too much in a hurry, but at first be sure you are right, and then go ahead.

One failure in this line will not only prove expensive fun to the concern who tried it, but it will prove a serious set back to the introduction of ice milk generally.

Just exactly as improper methods of pasteurization or production of butter from pasteurized milk and cream caused a failure and set back, and as also the introduction of an improper commercial culture for cream ripening almost put a full stop to the use of such cultures here. Therefore, let us fully post ourselves before we begin cream ripening with production of "ice milk" for city supply; it may seem very simple, and yet, as with pasteurization, it is much easier to fail than to succeed. J. H. MOLDENHAWER.

Washington, D. C.

The Tub Silo.

Methods of Constructing and Using.

First inscribe a circle to mark the outside foundation, which should be a few inches larger than the silo; then dig a trench for the foundation sufficiently deep to keep rats from digging under, or the foundation may be built on top of the ground, providing a cement floor is put in, which will prevent the rats from getting through and into the ensilage.

After the tub is erected, the corner formed where the tub rests on the foundation can be rounded out by filling up with mortar or cement, and the crevices on the inside of the foundation should be filled up so that the inside face will present an even surface.

When stone is scarce, one can simply dig an eight or ten inch trench and after the tub is set up in the center of the trench, fill in on each side of the staves with cement a little above the surface, so as to give some slope from the planks to the ground, and this will make a very neat and serviceable foundation.

The staves should be of 2×6 or 2×8 inch plank, not less than 20 feet long and planed on both edges. Some prefer to have them slightly beveled.

Now, the main question is the erection of this tub. It is the most easily done and with the least danger of accident by making two circles of inch lumber; these circles to be the size of the inside of the silo. Lay one on the foundation and raise the other about 15 or 16 feet above. This upper circle, if well secured, can be used for a staging. One man will be required to stand up the planks and occasionally tack the same to the lower circle, and toe-nail each plank to the one preceding it. A second man should work on the upper circle and nail and toe-nail the same as the man at the bottom.

As soon as seven or eight planks are up and securely fastened, the third man can commence work on top and carefully toe-nail the tops of the planks together. In doing this he should lay a few boards across the top to answer as a staging and by driving a few nails through these boards and into the ends of the staves, it will keep the tub secure and obviate the danger of a collapse in case of a hard wind before the hoops are put on.

As soon as the staves are all up the hoops should be put on. They are often made of flat iron, but ⅝ inch round iron is cheaper and stronger according to weight. They should be put on one at the bottom, the second two feet above, and the third and each succeeding hoop may have about one more foot of space between them than its predecessor.

A cheap board roof answers every purpose and can be put on without the use of a staging by waiting until the silo is filled. The boards should be sawed from corner to opposite corner, and by placing the sharp ends up a very nice circular roof can be built.

Place three or four rafters at the desired pitch and then by painting each two or three boards and bats as they are put on, the entire roof can be built and painted without the use of a scaffolding, as the ensilage answers this purpose.

A silo of this description, eighteen feet in diameter and twenty-six feet deep, holds sufficient ensilage to feed twenty eight cows for six months and costs only about $125 for labor and material, and when it gets a good coat of paint on the outside and a flag pole at the peak on which to raise Old Glory, it will be one of the most attractive buildings on the farm.—A. W. TROW, in *The Farmer*.

A Good Business Cow.

Prof. Robertson thus describes what he calls "a good business cow:"

"The cow in all civilized countries is always a boarder upon some person. She should be made to pay for her board at such remunerative rates as will leave a profit for the boarding-house keeper. If she fails in that, she should be made to render a service which she will not willingly contribute. Her carcass should be made into beef, and her hide into leather. She should not be shyly sent to board upon some other unfortunate man. A cow with the business habit of keeping her accounts with the world paid up, through the man who owns and feeds her, is a good business cow. That is the kind of a cow I recommend. Her power of service will be indicated by certain external points. She should have a large, long udder, of elastic, fine quality; a mellow, movable skin, covered with soft, silky hair; a long, large barrel, hooped with flat ribs, broad and wide apart; a broad loin, spreading out into broad, long hind quarters; an open twist, with rather thin hips, and a lean neck of symmetrical length, carrying a clean-cut, fine face, with prominent eyes. A cow with these points has ability to serve a man well, if she gets a fair chance. That her calves may have powers equal to, or rather better than her own, care should be exercised in their breeding. The best blood of the breed adapted to the farmer's purpose should be used to enlarge and not to lessen, the working capacity to be transmitted to her calves."

GUERNSEYS FOR SALE. The increase of my herd is a few young things of both sexes, from one to eighteen months old. Prices corresponding to age and quality. F. W. TRATT, Whitewater, Wis.

FAIRVIEW FARM GUERNSEYS. FOR SALE—Yearling Bull, BEAUTY'S KING 5301. Sire, King of Kenosha 3706. Dam, Kenosha Beauty 5293. Grandson of Benjamin and Squire 4th. Also younger bull calves of good breeding. Address C. W. WILCOX, Des Moines, Ia.

GUERNSEY Cattle—SHETLAND PONIES.—Old Homestead Herd was Champion at O., I. I. and In. State Fairs, 1898, winning against well-known O., Pa., and N. J. Guernsey show herds. Over twice as much prize money as all competitors combined at above fairs No better collection in America. Breeding Stock for Sale. Inspection invited. L. V. AXTELL, Perry, Lake Co., O.

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

SHADY NOOK HERD Holstein-Friesians Choice Chester-White Pigs 2 to 3 months old, both sexes, for sale. W. R. GATES, Ripley, Jefferson Co., Wis.

Registered Holstein-Friesian Cattle. Best families of the breed. Aaggies, Waynes, De Kols, Netherlands, Pauline Pauls, Pietertjes. WM. O. JACKSON & SONS, South Bend, Ind.

HOLSTEIN-FRIESIAN CATTLE

Owned by JONES & RANDALL, Hustisford, Wis. 100 head to select from. From families rich in butter fat. Herd now headed by Barron Paulina De Kol. Stock for sale. Prices reasonable.

HOME FARM HERD.

Headed by Jewel of Home Farm, Sweepstakes Holstein-Friesian Bull Trans-Mississippi Exposition Omaha, Neb. Seventy-five head to select from. W. B. BARNEY & CO., Hampton, Iowa.

MEADOW LAWN HERD Holstein-Friesians.

Herd headed by Sir Brookside De Kol. Choice young stock for sale. Come and see them. C. W. HARRISON, Ringwood, McHenry Co., Ill.

HOLSTEIN-FRIESIAN BULL CALVES From advanced registery and officially tested, prize-winning dams, as high as the 21-lb. class, 70 to 76 lbs. milk from cows. Quality as well as quantity. If you want *the* best address MALCOLM H. GARDNER, Darien, Wis.

PARTHENEA.

Butter record 38 lbs. 8½ oz., in seven days, thus the second highest butter producers of the breed, that sold for $2 000 and won many prizes at the leading dairy shows, in milk and butter tests and the show ring. She is the dam of Parthenea's Colanthus 15597, the chief stock sire at head of this herd for many years and that sold for $1,000, and proved to be a greater sire of fine show stock an great butter producers, than his unequalled sire, Colantha's Sir Henry and grand sire, Sir Henry of Maplewood. For prices of this blood address VALLEY MEAD FARM, Monticello, Wis.

Early Cut Hay.—Corn as a Catch Crop.—Cost of Rations.—Kentucky Anti-Color Law for Butter.—Colored Cheese.

ED. HOARD'S DAIRYMAN:—The up-to-date dairyman here about, had his hay all, or nearly all, well secured in his barns before the first fire cracker awoke an echo, July 4th. It was all "just right," and was secured without being injured by rain. The old timer "way back fellow," however, is just now well "started in." He don't believe, he says, in "puttin' in such green stuff;" wants "heart" in his hay. Well, he is getting it, and with it all the rain water he wants; for since the last week in June, we have been surfeited with it, and thousands of tons of hay in cocks, windrows and mower swaths, have been nearly ruined thereby.

This week, however, has been more favorable, as but little rain has fallen so far.

The hay crop in Old Ellesburg is, or was, a good one, especially on last year's clover seeding. Some old meadows, however, are light; but I know one farm, where fifty acres have been cut, that produced fully one hundred tons, largely of clover, and it is all in one barn, too. That clover and the big field of Leaming corn ensilage, which is now growing, and which is to go into a 300-ton silo, doesn't give the proprietors much pause, because of a prospective shortage in next winter's fodder supply for the forty cows, a half dozen horses, and thirty or forty head of young things.

But "there are others" who have no silo, and whose old meadows were so thin that they made haste to secure the crop, then at once plough them and put in corn. But those fellows are not feeling quite so sanguine. An untimely September frost, you know, may nip that corn in the bud, and thus blast the hopes of the planters, unless the stuff is cut before it matures.

Corn, though much of it was planted late, is very promising, the warm weather and frequent showers having given it a Klondike boom.

Winter wheat, which is now ready for the binder, is a good crop, while spring grain and potatoes give good promise of large yields. All in all, this old town has no reason to put up any calamity howl, because of bad crop prospects this year.

I note the J. B. Phelp's article, page 437, of your July 14 issue, in which he supplies the "missing links" in the *Tribune* writer's ration formula, and which I was glad to read. I could not see how, if man "cannot live on bread alone" even if he is so fortunate as to get it, a cow could live on ensilage alone and produce milk in Pennsylvania. Mr. Phelp's explanation, however, solves the problem. But his prices for foods, except those for silage, are too low for this market, this year, even, and far too low for the year in which that cow census was taken.

This year, good, early cut hay is now selling for $10 per ton. Wheat bran is worth $16, and cotton seed meal $22. Quite a difference, you will perceive.

But Mr. Phelps does not tell us what his pasture cost of keep was, how many weeks or months his cows were fed the ration he names, or how long they were in milk. The averages I gave in the census were for a full year. I hope that Mr. Crawford will let in the light, as has Mr. Phelps, as, doubtless, the *Tribune* man is as wide of the mark in the one as the other statement.

According to the *Jersey Bulletin* its uncolored butter millenium is in sight, the Kentucky legislature having worked the first degree in the law. Hereafter, colored butter, including that from the World's Fair Jerseys, will cut no ice in that old Bourbon, blue grass state. The poor devils—and the rich ones too— down there, must, hereafter, eat the pure, transparent "critter," just as it appears when it first sees the light, or else eat lard or oleo, on their biscuit and rolls; and the *Bulletin* is so rejoiced at the prospect that it rubs its hands like another Uriah Heap. The chances are that more oleo will be eaten in Kentucky now than ever before, as the oleo men need have no fears. They can ship their uncolored fraud, and sell it beside uncolored Jersey, Holstein or any other cow's butter, fearing no evil consequences.

If anybody ought to be happy because of this Kentucky anti-color law, surely they must be the Chicago and Kansas City men, as they will now have a walk over in Kentucky. No doubt their money was the lever that moved those legislators to answer the prayers of the *Bulletin* and some of its writers.

When enough such idiots shall have been congregated in the legislatures of the remaining states, and asinine governors enough are elected in sympathy with them to put such legislation on all our statute books, the old cow's occupation, except to produce steer calves, will be gone, and she relegated to the retired, or *tired* list.

Such legislators, however, will wake up, if they try that little game in this state, to find the consumers of butter are going to have a hand in the business. As yet their tastes have not been developed up to the point of being forced to eat uncolored Jersey butter or white oleo on their bread.

But what are the cows to do in June when they must color their butter, whether they will or not, and at what season must the line be drawn between natural colored and artificially colored butter? And what an army of chemists there will have to be employed to separate the wheat from the tares.

But why not enact a law preventing the coloring of cheese? Is not that done to hide dirt and poor quality, and is there not danger of some one being "worked off" from having eaten the stuff? Why not? The same coloring matter is used in one as in the other.

True, there are certain consumers who say: "We want some vegetable coloring matter put into our cheese at all seasons; and, in certain seasons into our butter, not to hide filth, nor bad flavors, nor odors, but to satisfy our whims. We don't like the appearance of white butter or cheese, but prefer a yellow tint. If you cannot, or will not, furnish it for us, we will look elsewhere for it."

Such people will get what they want, if they have to import it; and it will be a chilly day for the New York dairymen—if such an one ever dawns—when it shall become a misdemeanor to tint either butter or cheese with pure vegetable coloring matter. There are a whole lot of them, quite a contingent of whom are Jersey and Jersey grade owners, who will brook no such clap-trap legislation.

They know that butter is never colored to deceive any one as to its quality, nor to imitate any other product. It is the nose and palate that are the judges when butter is put on trial for quality; just so with cheese, the adding of coloring matter will deceive no one. It is done because the consumer demands it, and no one but an idiot, or one who has some selfish or dishonest motive at heart, will assign any other cause for it.

Belleville, N. Y. C. W. JENNINGS.

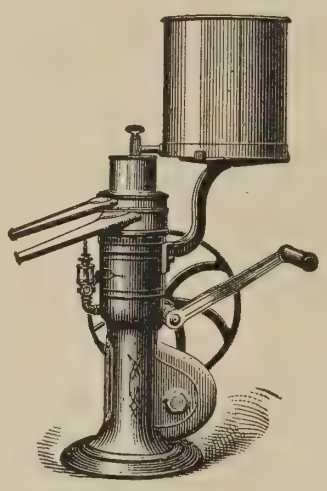
Notes From Southern Pennsylvania.

Clover and Timothy.—Acres per Cow.—Dairying in Pennsylvania.—The Cow and Her Owner.—Creameries.

ED. HOARD'S DAIRYMAN:—In the main we have had a favorable season, thus far. Our spring was rather late, but when it came it was very warm and all vegetation was pushed forward very rapidly. Considerable of the early planted corn and even some of the late, germinated very poorly and the stand is very uneven, but extra good weather has pushed it forward, so that now the prospects are very favorable for a good crop. The oat crop will be very large and heavy. The wheat crop was almost ruined by the fly.

Owing to the very hard winter, about all the clover was winter killed last winter and spring, and the result is all timothy hay, which will be cut after harvest and will make poor cow feed. The average hay crop will be rather light, though with a good corn crop our farmers will have plenty of roughage. Thus far this summer the pasturage was plentiful and the creameries have a large supply of milk.

The great majority of our farmers depend on pasture the entire summer. Turn the cows out about May 20 to June 1, and expect them to hunt for their feed until frost kills all the grass. If the weather is in their favor, the cows will give milk, but as soon as the rain fails, the milk fails too. Every farmer keeps a certain number of milk cows but by this method the average for quite a large territory of south-eastern Pennsylvania is one cow to fifteen acres of tillable land. Of course, there is a light sprinkling of persons who have received some inspiration from



The One Successful Color

IT gives entire satisfaction and is the only color that buttermakers should use. It is the one color found in over ninety per cent of the creameries of the country. Butter containing Wells, Richardson & Co.'s Color has the highest standing in the markets. . . .

HOARD'S DAIRYMAN and other good papers, and are trying some modern methods to make dairying pay on the farm. Some few provide spring and summer crops and practice partial soiling and still fewer have silos. The great majority of cows come fresh in the spring and by the time the summer drouths and fly pest are at an end, the cows are very nearly dry. Running over browned pastures and fighting the flies is not very conducive to keeping up the flow of milk.

Co-operative creameries are almost unknown, though we have a few successful ones. All the milk away from the main lines of railroad is worked up into butter by private creameries. The majority of creameries use the Babcock test, though many still pool the milk. Prices are quite low, as there is no competition.

During the months of June and July the pay was 14 to 15c per pound of butter fat, while Philadelphia quotations were 20c for fancy prints.

Along the main lines of railroads, milk stations are being established very rapidly, and that with the creameries furnishes some "life of trade," and the prices are considerably higher to the farmers. Creameries in that territory were paying 18 to 18½c per pound for butter fat, while the others were paying 14c.

We have many mining and manufacturing towns, and all those in reach of these markets, market their own dairy products and find it very profitable to do so. Prices for milk and butter are good almost the year through. In fact, we have all the facilities here in southern Pennsylvania that go to make dairying profitable, except one item, and that is the know how, and, Mr. Editor, it is a big item Eighty-five per cent of our cows are scrubs, Durham or Short-horn grades, general-purpose, all purpose, dual-purpose, nondescript stock, producing milk four to five months in a year, but eating good full rations the whole twelve months.

We have good land, good water and, as a rule, plenty of feed. Please don't put us in the list of feeders quoted by friend Jennings, on page 397, as south-eastern Pennsylvania is populated mostly by Pennsylvania Germans and Quakers, and they are lovers of big, fine, fat stock and are very liberal feeders. You know, Gen. Lee, when he invaded our territory during the "late unpleasantness," said the Pennsylvania Dutchmen had the biggest red barns he ever saw and in them big fat horses, almost as big as the barns, and to prove his assertion to the folks at home, he just took them along.

In years gone by, when eastern beef production was yet profitable, we excelled in the production of fine export beef cattle. But beef making was not profitable of late years and all farmers turned their attention to feeding milk cows, and thus it comes about that we have such a large percentage of meat producing animals fed as the old beef animal was fed,—plenty of timothy hay, corn stover, and corn meal, as much as they will consume. Instead of a four cent per day ration, it costs most of us three times that much or more.

Our people have so long kept the large beefy animals that it is a hard matter for them to part with them, but one or two examples go a great way.

Some patron of a certain creamery looks up dairy matters in our modern dairy press and very soon purchases a good dairy sire and possibly a few heifers or cows and in a year or two, you have no idea how that man's creamery check rankles in the hearts of all his neighbors, who believe in the general purpose cow. Such living object lessons do very much good. Whenever I find one of these missionaries, if I sift the matter down, it in nearly every case turns out that some time back he "run across" a copy of HOARD'S DAIRYMAN and that started him to thinking.

Not only is it the farmer who lacks knowledge, but the majority of our creamerymen also. An occasional creamery turns out a first-class article, but the large majority of our creameries are owned and run by people who know very little or nothing of the production of first-class butter, such as is wanted by the best paying customers and in the end the farmer has to bear the loss of their ignorance.

Oh! It is an awful tax we have to contend with, this paying over and over again to learn and still we persist in the old ruts. There is a little paragraph of about a dozen lines on page 389 of the DAIRYMAN, headed "Got Rich at Dairying" that tells an encouraging and doubtless true story but I have no fears that the columns of the DAIRYMAN will be over burdened by reports of that nature from our section of Pennsylvania. This whole question of making money at dairying or making nothing, resolves itself into a simple problem of the difference between intelligence and ignorance. Where intelligence exceeds ignorance there is a profit; where ignorance exceeds intelligence there is a loss. It often pays us to work a little less with our hands and think a little more with our brains. Any strong man can sell labor and it is a drug in the market; but not everyone has skill and intelligence for sale and it commands a premium.

Adams Co., Pa. L. W. LIGHTY.

The Cow Not Wholly a Machine.

Commenting upon the effect of changing milkers at the Kansas Experiment Station, where, contrary to the general rule, an increase in the yield was observed, Mr. J. A. Conover says:

"We are inclined to think that whether there is an increase or decrease will depend upon the kind of person that the new milker is. If kind and easy with the cows they will increase, and if he is rough, talks sharp and harsh, they will resent such treatment by a decrease in the milk.

The cow, after all, is a machine only so far as the converting of raw material into a more finished product is concerned. In every other sense she is very much alive, and is very much influenced by her surroundings and the treatment she receives.

Harsh treatment and poor surroundings will make the best cow poor, and kind treatment and good care will make a poor cow much better."

All About the Farm.

Forage and Fertility.

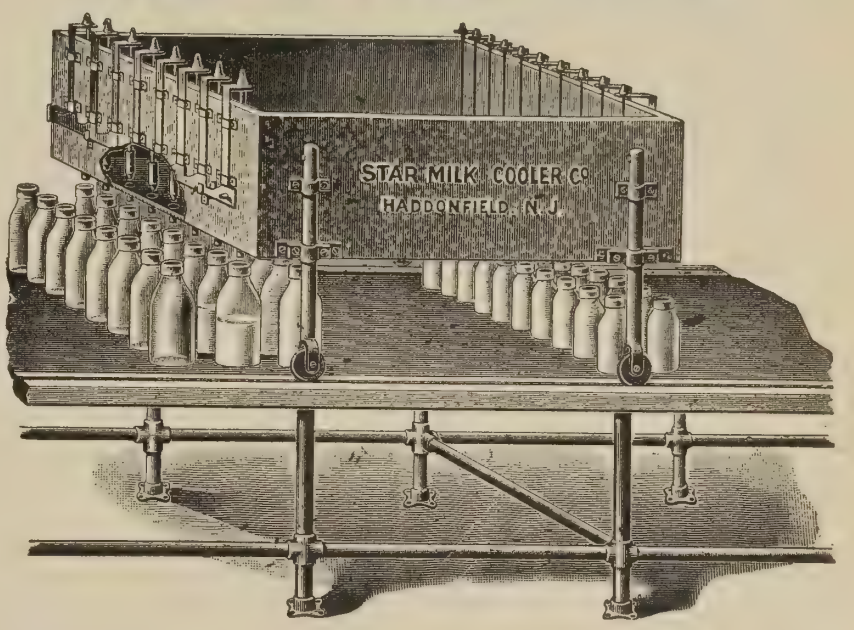
We are at the commencement of a great war; not against any foreign foe, yet one equally to be dreaded. It is a relentless war, without quarter, to the knife, and the knife to the hilt, against the fraudulent manufactures which are the curse of the dairyman. During the month of December, 1898, in Chicago alone, 91,000 tubs, 50 pounds each, of oleomargarine were manufactured. During the last six months of the same year, 384,000 tubs of equal weight were turned out upon the world. The dairy industries of the great Empire state must be saved. The task is intrusted to the mighty army of young men. Theirs is the fight and they are armed with the ballot.

Not one-half as much milk is being used in the state or country as would be if the right laws were properly enforced. To fight these frauds is one of the duties of American citizenship. Why tarry? There should be no deterring considerations. Friends, bank account, the desire to make money, should not count; fight. Knowledge is everything; struggle from now on for an equal place with the manufacturing world. Up to the present there has been little struggle. Most dairymen practice "mining agriculture," that is, taking out the value from the soil. There should be no more surface mining. From now on, more money can be made out of agriculture, correctly employed, than ever before. This is a great state; there are no products which cannot be grown within our boundaries at a profit. Think of the demand which will prevail 50 years hence, and be ready to cater to the increase. Fertility is nothing, productiveness everything. The beginning of economical agriculture is the feed of the cow. A 1000-lb. cow wants 35 pounds of clover hay. It costs about $24.50 to feed her in the winter and $6 for summer pasture. Let the dairyman study how to best get this feed.

Much soil is lazy and does little. Potash is generally wanted, yet there are potash mines in the soil. Learn the philosophy of tilling. In the recent analysis of samples of Jefferson Co. soil 5.59 per cent of potash was found. This is six and a half tons to the acre. It is formed by the disintegration of the bluffs. As quickly as one learns to utilize the richness, the soil will produce manifold. Indian corn is the king of the plants. It was growing when Hudson sailed up the river bearing his name. It is king; always was and always will be. Many dairymen, by hard work, secure one ton of dry matter from the old meadows. Grow corn and get four tons. We buy our bran from Minnesota and our gluten from Mississippi and soon use up the value of the land. Raise these things at home. Use correct methods. One might as well sow a peach orchard broadcast, as to sow a corn field broadcast.

Do not be afraid of exhausting the fields; they cannot be exhausted if used properly. Grow something, pig weeds or thistles, if nothing else; don't have bare ground. Study environment; study the refuse question intelligently. Properly saved and properly applied, it is a factor of primary importance. If a farmer should come home and find a hole in the grain bin and the grain running out into the mud, he would not stop to inquire whether he should stop it with a hickory or hemlock plug, yet the majority of farmers will stand by and see the strength of the manure piles running away with the rain. Utilize every home resource first; then if MotherNature will not smile upon your efforts, use fertilizers.—Prof. Roberts, in *Orange Judd Farmer*.

The Guernsey Breeders' year book for 1899, just published, contains the results of the 1898 home butter tests. These are the most complete milk and butter records ever published. Ten Guernsey cows now have records of over 10,000 pounds of milk each year, and 140 cows produce more than 400 pounds of butter per year. About the same number have records better than 14 pounds in one week. The book contains much interesting matter on the percentage of fats and solids in Guernsey milk, and shows that the Guernsey is an economical producer of milk and butter. It is published by Sec. W. M. Caldwell, Peterboro, N. H.



Gluten Feed is used by nearly all successful dairymen, and has become a necessary article for any dairyman farmer who wishes to keep pace with the successful men in his line of business.

Gluten Feed increases the flow of milk, improves the quality, keeps the cattle in the best possible condition—in fact, helps you make more money out of your dairy. This is not cheap talk. We mean business. Gluten Feed is all and more than we claim for it, and, best of all, a trial proves it. Sample of Gluten Feed, Milk Talk Pamphlet, and circular illustrating the "Value of Butter Fat in Milk," all FREE if you address

Seasonable Notes from Michigan.

Churning, Gathering, Salting, and Packing of Butter.

ED. HOARD'S DAIRYMAN:—A question in regard to gathering butter in granular form came to me from a North Carolina lady, who writes as follows:

"We are told to draw off the buttermilk when the granules are the size of wheat kernels. After doing this and sending the buttermilk to town, I find more butter has gathered into lumps in the course of its travels, showing that I have lost butter in my mode of following this practice.

"Then if butter is to be separated from the buttermilk before the former has gathered into one large lump, how is it done? Is the buttermilk strained? If so, through what?

"Will you kindly tell us how you make those movable mangers? Would like an exact description of them."

The movable mangers will be described in a future number; the butter question seeming to need immediate attention.

The fact that butter accumulates upon the surface of the buttermilk during its journey to town may be owing to any one of several causes. One of these, and one which occasions loss in a great many instances, is the practice of adding sweet cream to that which is sour within a few hours of the time it is put into the churn. Such cream does not have time to become thoroughly ripened, consequently is not so readily converted into butter. When the fat in the other cream becomes separated, that from the sweet cream has not yet reached the separation point. If this is the case in the present instance, the shaking up which the buttermilk receives on its way to town finishes the churning, which would account for the additional amount of butter.

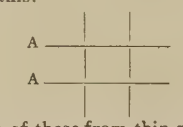
We all know that it takes longer to churn sweet or partially ripened cream than that which is sour, and while a portion of the butter from the former might be secured, it is evident that considerable would remain unchurned when the other became visible. Another cause of the second gathering of butter might be found, indeed has been repeatedly found, in the cows being at different periods of lactation.

The new milch cow's cream is much more readily converted into butter than that from the stripper. I have known two distinct batches of butter to be secured from the same churning for this reason alone. Not content with the amount first secured, the buttermilk was churned with good results. In a small dairy, this sometimes gives considerable trouble.

Where there are a goodly number of cows, fresh or nearly so, the difficulty is overcome to quite an extent, since the more viscous milk and cream of the strippers is diluted by that from the others, and rendered more churnable.

This also is an aid in securing all the cream, when the gravity process is employed. It is well in dealing with the milk from farrow cows and strippers to add water to it when setting. The fat globules do not so readily find their way to the top in the milk from such cows, its viscosity retarding their movements, hence the desirability of diluting it, either with the milk of fresh cows or with water.

In making butter by the granular process, the beginner frequently is troubled to get a good separation of the butter from the buttermilk. In our own practice, the buttermilk has always been fed to pigs, aside from that used in the kitchen. For this use it matters not if it is salty. We have found that by adding salt and water to the contents of the churn when the butter begins to break, a much better separation can be obtained than without this. For a forty-pound churning a pint cup of salt in a gallon or so of water acts like a charm in sending the granules to the surface.



There will be some particles washed out in drawing off the buttermilk, and in the rinse water, and to catch these a strainer of some kind is required, or they may be removed from the surface with a fine skimmer.

A common cream skimmer is as good as anything for the purpose; simply skim them off and put back into the churn. If they are very fine, too small to be caught in this way, the temperature is too low. In winter this sometimes occurs, the particles of butter being as fine as corn meal.

To warm the rinse water to 60° or 62° will do away with the difficulty.

Buttermilk strainers can be bought of any dairy supply house. These are not expensive, and are very satisfactory. Being made of horse hair, butter does not stick to them, so there is no clogging, as is the case with a common milk strainer when used for this purpose.

A home made buttermilk strainer, which answers every purpose, is made of bleached butter cloth. A frame for holding it is, in shape, like this:

Make two of these from thin strips of wood and connect by leather hinges at A, A. Around the center part of one-half, drive small nails, the points of which protrude sufficiently to catch and hold a cloth placed over it. Shut the two pieces together and lay over the top of a pail. The butter will be caught as the liquid passes through. The frame should be just long enough to place across the pail nicely. The cloth which composes the strainer is taken out each time it is used and thoroughly cleaned.

The process of making granular butter is one requiring great care on the part of the operator. Attention to detail is necessary throughout, and a proper temperature maintained. Low temperature results in exhaustive churning, although the time required to bring the butter is greater.

A Babcock test is very useful in disclosing loss of butter fat, both in the skim milk and in the buttermilk.

Granular butter rightfully takes first rank at the present day. In theory, the process of its manufacture is correct for best results, and when carried out it is not found lacking; practically, it maintains its great superiority over butter made in the old way.

I have never found a person who, after practicing this method, was willing to go back to the old way, but I have known a good many who were so deeply imbedded in the rut of habit, and attached so firmly to old-fashioned methods, that they were unwilling to try anything modern, which in any way conflicted with their present practices.

I notice in a recent issue of the DAIRYMAN, something in regard to keeping butter in brine to preserve it for future use. We have tried this method, and think it is the best we know of. Make the butter into rolls, carefully wrap each in butter cloth—don't use old muslin which has done duty in other ways when the other is so cheap—and place in stone crocks. Cover with strong brine which has been boiled and allowed to become cold. Keep entirely under the surface of the brine, by means of a weight.

Owing to the shape of the rolls, these cannot be packed very snugly, and but few will go in a crock of ordinary size. We have two twenty gallon stoneware crocks, which we keep for pork and beef, instead of using wooden stave barrels for this purposes. In summer one of these is usually empty, and we found it an excellent thing to keep the rolls of butter in, on the one occasion when we put it up in this way.

In addition to the salt, it does no harm to add a little sugar and powdered saltpetre to the water, say a tablespoonful of the former and half as much saltpetre to six quarts of water. Butter put up in this manner has been known to keep sweet and good for a year. The main point is to have the brine strong enough,—use all that the water will dissolve.

The especial reason for wrapping each roll with cloth is to preserve the color of the butter; placed in brine without the cloth around it, it turns lighter on the outside.

Speaking of these large stone crocks, I want to say that we would not return to the wooden barrels for meat, after using them. They cost eight cents per gallon here. They are very heavy, it is true, which is some-

CONCERNING OUR ADVERTISERS.

Our readers will be interested to know that the American Well Works, of Aurora, Ill., are now putting a new attachment on their "Elliptical" Well Drilling Machine, with which they use steel wire cable instead of Manila rope for rock work; this also includes the wood drilling pole system. Write them for particulars.

More corn is cut by the simple Steel Corn Cutter, of the Dain Mf'g. Co., Carrollton, Mo., than by any of the other cutters known, however much higher priced the others may be. The reasonable price is a decided and valuable feature of the Dain. Prices and special information free to all who write the makers. See the ad in this issue.

The readers of HOARD'S DAIRYMAN are extensive buyers of milk cans and all kinds of dairy tinware, and we are positive it would be a great saving to them if their purchases in this line were more confined to the best known goods. There are but few that can correctly judge quality by examination, and a very safe course is to buy those goods that have well known reputations for quality. The Buhl Stamping Co., of Detroit, Michigan, have for years been advertising in the DAIRYMAN, and now are, and it is safe to say that there is no better line of dairy tin-ware made than is made by them. The large quantity of their goods that they make, coupled with their years of experience enable them to turn out goods that for same cost are seldom equalled. It is a safe guarantee of quality to buy stock of their make. They study to please their trade and make cans of unusual strength, and free from crevices, black spots and roughness inside, which makes it possible to keep the cans clean and pure. These cans are made of steel, heavily coated with pure tin, so that they will not easily dent up or rust. They have recently placed on the market their new cans styled the Sunset, Sunlight and Jersey, medium priced, claiming for them, and they will stand by their claim, that they are the best cans for the money that can be placed on the market. They have issued a little book, "A Study in Milk Cans," that would be interesting to any reader of the DAIRYMAN, which they will send postpaid on request, mentioning HOARD'S DAIRYMAN.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

LUMP ON FOOT.

Can anything be done to remove bunch on heifer's foot, that has been there a year or more. It is as large as an average sized apple. She hit it with her foot and cut it so it bled, and the inside looks like cut flesh. It is on the top of foot snug to the hoof. It does not make her lame. M. J. S.
New Market, N. H.

ANSWER.

I fear treatment will not remove the tumor, and it might increase the size, instead of reducing it. Seeing it does not affect her at all, I would let it severely alone.

CHRONIC LEUCORRHŒA.

I have a chronic case of leucorrhœa or catarrh of the womb. I wrote you last December, about it; and you prescribed Bromo Chloralum; that did not stop it. I thought then she would come right in time, without any treatment; will they do this, if so, how long are they liable to run? The past month I have been using another of your prescriptions—a wash of cloride of zinc, glycerine and water, also the nux vomica, gentian, ginger, and whisky, taken inwardly, but she still discharges.

She is milking well and looks well, but of course does not "come in heat." W. C.
Wyoming, Wis.

ANSWER.

Neglected leucorrhœa never gets well, but gradually and surely worse. Introduce a cow catheter into the womb and draw off all the fluids, then wash out with tepid water introduced through the tube and then inject one ounce of Bromo Chloralum to eight of water. Do this twice a day until not needed. Alternate this with one dram of sulphate of copper, five ounces of glycerine, and one pint of tepid water. Repeat this daily until the catarrh is stopped.

Be careful to thoroughly wash the vagina at each washing. Do this carefully; by no means scratch or otherwise irritate the skin of the vulva. Use soft, clean hands and well pared fingernails in handling the parts. Let her lie slanting behind for a while, not too much.

LEAKING MILK.

I have a heifer that loses her milk. When she walks the milk runs from her teats.
Lebanon, Ohio. J. F. M.

ANSWER.

Leakage in the manner named, is a bad fault always, as it is always bad to manage. I know no way to do, as good as the use of a rubber elastic band of such a capacity of strength as to just tighten up the end of the channel at the end of the teat. Don't have it too tight; as there is but little circulation at the end of the teat, no discomfort need be felt.

PERHAPS LUMP JAW.

Have a heifer, one and a half years old, whose jaw seems to give signs of lumpy jaw. A swelling at the base of the lower jaw, about the size of a butternut, has aroused my suspicion, especially during the last few days, as the swelling is becoming larger. The animal is a high grade Guernsey.
Wis. A READER.

ANSWER.

Can't say what the real nature of the disease is without examination. All such symptoms are of a grave, suspicious nature and require a genuine expert to make a close and scientific examination. Lumpy jaw, actynomycosis, is incurable and if it was curable in a subject, it would be a crime to breed from such contaminated individuals.

CHRONIC GARGET.

We bought a Holstein cow last winter; one of her hind quarters cannot be milked by hand, always use a tube. It seems to be an old case of garget, a hard piece remains in it after it is emptied, which prevents getting hold with full hand, as her teats are not very long. She gives almost as much milk out of that quarter as with the others.
D. J. De H.

ANSWER.

You have a hard and chronic case and there is little hope of a cure, but you can try the following: Internally, give seven grains of iodide of potassa in a little cold water as a drench each morning for ten to thirty days, as may seem to be needed. Outside, over the hard spot, only, paint with strong tincture of iodine three times a day, for several days. If it gets sore, cover with hog's lard until the scabs are off. Then repeat, etc.

SORE SPOT ON BACK.

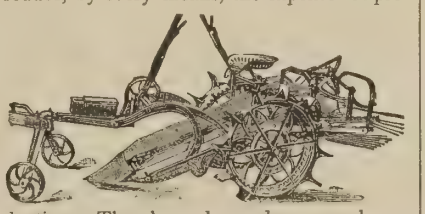
My horse has a soft spot on his back about six inches in length. There seems to be some fever. Am inclined to think the spot is spreading. C. A. P.
Spanaway, Wash.

ANSWER.

I can't possibly give you any advice as to a correct diagnosis from your meager statement. I suppose a good, strong liniment would be a good application, but am not positive. Oil of cedar, one ounce; sulphuric ether, one ounce; fish oil, four ounces. Keep well corked and out of the sun. Rub in well twice a day for a while. Shake before using, always.

UMBILICAL HERNIA.

We have a Holstein heifer calf, about three months old. It has a rupture at the navel about the size of a half of a cocoanut.
Muscoda, Wis. A SUBSCRIBER.



ANSWER.

Umbilical hernia is usually reduceable, but always needs the doctor for the operation. No form of correspondence can avail in any such cases. The younger all such operations are performed, the easier it is to succeed.

ILLUSTRATION.

POTATOES AS A MONEY CROP.

There are but few crops grown in this country that produce more actual money to the grower than the potato. This is so notwithstanding the fact that, taken as a whole, the most primitive methods are still employed in growing and marketing the crop. As against this general condition there stand out here and there with special prominence those cases where potatoe growing is reduced to an exact science and where the best and most improved appliances are used in the labor connected with producing the crop. These people have learned that the way to produce the greatest profit is to reduce, by every means, the expense of pro-

duction. They have learned, or are learning, with the manufacturer, that the expensive element of hand labor must be reduced to the mininum if the resulting product is to leave a margin of profit.

To dig or harvest a crop of potatoes cleanly, easily and rapidly, in the nick of time when the weather is at its best, is a very expensive and laborious job when the work has to be done by hand. Happily for the farmer or special potato grower, there are now machines that will perform this labor in the most perfect and economic manner.

A machine of this kind, possessing special merit, and which has been long and favorably known to the public, is the Hoover digger, manufactured by Hoover, Prout & Co., Avery, Ohio. This machine is built upon honor and sold upon its merits. Write these people for catalogue, prices, etc.

Horse Owners! Use
GOMBAULT'S
Caustic Balsam
A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from **Horses** and **Cattle. SUPERSEDES ALL CAUTERY OR FIRING.** *Impossible to produce scar or blemish.*

Dairy Talk in Maryland.

No matter where we go, whether in Maryland or elsewhere, the essential principles of dairy practice are the same. And yet there are thousands who object to the taking of a dairy paper published in another state on the plea that it is not adapted to their locality.

At a recent Farm Institute in Maryland, Mr. Edward Van Alstyne, of Kinderhook, N. Y., a fruit grower, dairyman and cultivator of 400 acres of land on the Hudson River, gave a practical talk on dairy farming. He spoke particularly of the dairy cow and her feeding; of butter making and milk production. Mr. Van Alstyne said in part:

"Many men are keeping cows just for the sake of keeping cows, without knowing what kind of cows they are. The milk trains from New York city, are stretching out for 400 miles, and the buyers of milk are paying more a gallon for it than do the cheese manufacturers or butter makers. The Western people are sending their butter and cheese into our great markets and our people have to compete with them and must sell their products at market prices or they must go out of the business. It is necessary to increase the products of the cows. You must have good cows in order to produce milk profitably. If you are going to produce milk, beef or butter fat, you must have cows suited to such production."

Mr. Charles A. Councilman—In this section we are obliged to sell milk at a gravity test.

PEDIGREE NOT ALL.

Mr. Van Alstyne—The gravity test is the most deceiving thing I know of. I do not care if a cow has a pedigree a mile long, if she does not have individual merit she is no good. There is no objection to a pedigree for then you can get better prices for the offspring. The first requisite in a cow is a good, strong constitution, a cow that has bright, clear eyes and that can digest her food properly. A cow that is too lazy to get up when you lay your hand upon her, is inclined to put on fat rather than to give milk. A good milk producer has an arched rather than a straight back, and the milk veins should be large and crooked. The skin should be soft like a glove, and a cow that has an oily indication is the cow to produce butter fat.

After you have a cow to suit, it is very important that care should be taken in the feeding. Many a good cow is not producing what she ought, because you are not giving her a chance. You are not giving her enough to eat. Feed is more important in summer than in winter. Pasture does not furnish all a cow wants in summer. She should have some supplementary feed. Don't feed too much grain. If you give a cow more grain than she can digest, you are not getting the benefit of it. Shelter is also important. I don't believe it is wise or a good thing to keep a cow in the stable all the time in winter. The air that comes through a window is not like being out in the open air. I don't care for a cow to go dry more than six weeks. I don't believe in cutting up hay for cattle; put it in the rack.

The Cost of Making a Pound of Butter.

The annual report of Dairy Commissioner Norton, of Iowa, proves quite conclusively the point which we have frequently argued, that the cost of the manufacture of a pound of butter in the creamery is almost entirely governed by the quantity of milk handled by that creamery, and that a decrease in the cost, on account of the magnitude of the business, is followed by an increase of the price paid to farmers for butter fat. One creamery in one of the dairy counties in the state manufactured 400,000 pounds of butter at a cost of 1 cent per pound; another 539,000 pounds of butter at a cost of 1.2 cents. In the smaller creameries the cost is reported at from 5 to 7 cents per pound, the average being 3 cents. In creameries handling not more than 2,250,000 pounds of milk, the average cost is 2.42 cents, and when 1,000,000 pounds are added, the cost falls to 2.2 cents, while in creameries receiving more than 3,500,000 pounds of milk, the average cost is 1.79 cents. This explains why it is that dairymen prefer to locate in dairy counties. It means an increased price of from 1 to 2 cents for butter fat or an increase from 8 to 10 per cent. Land, therefore, in these sections, sells higher because there is a home market and the highest price for its principal products.

This explains, also, why creamerymen in sections where dairying is not a specialty, are compelled to give lower prices for butter fat. In many of these places the cost of manufacture is from 4 to 5 cents per pound. This is taken, necessarily, from the producer, and this also explains why skim stations prevail in these districts. It is cheaper to pay the express rate on cream from a station to a central factory than it is to run a creamery at the station. Where a creamery is established, every farmer who patronizes it, or intends to patronize it, should exert himself to the utmost to increase the supply of milk to the creamery. In so doing he will cheapen the cost of manufacture, and thus advance the price of his own cream. The attitude of a few leading farmers is frequently the life or death of a struggling creamery in a new country. If these men throw their active support to the creamery, they can increase the supply of milk and thus enable the creameryman to give an increased price. This increased price renders it comparatively easy to secure still further patronage, and, in time, an industry profitable alike to the farmer and the creameryman will be built up; but if they withdraw their support and discourage their neighbors, they decrease the amount of milk and decrease the price, and frequently compel the creamery to close or become a mere skim station.—*Wallace's Farmer.*

An Experiment in Liming Pastures.

The Effect on the Quality of the Cheese Produced from Such Pastures.

The following, taken from the last issue of the *Dairy*, London, England, shows the effect of lime on the quality of the cheese, where cows were pastured on land on which this material was used:

"It is generally believed that land which has been stocked with sheep is injurious for cheese making, and can be materially improved by liming. Two fields, which had in the past been heavily stocked with sheep, were selected for an experiment on liming. The orchard (in which the cows were milked) was also limed, so that the cattle could be both kept and brought home to milk, on land which had all been limed.

"The method of experimenting was to keep the cattle for a certain length of time on the limed land, Fields 1 and 2, and then for a similar period on the unlimed land, Fields 3, 4 and 5, and subsequently on the limed land.

"The lime was considered to have produced a marked improvement in the herbage. Its effect was also noticeable in the cheese tub, inasmuch as the curd seemed firmer and better than it was when the animals were on the unlimed land. But neither chemical nor bacteriological examination showed much difference in the curd. The quantity of the milk was not appreciably affected, nor was its composition affected to any extent. The acidity of the milk appeared, however, to be affected to some slight extent, the milk, when the cows grazed on the limed land, showing a slightly higher acidity.

"Analyses were made to determine whether there was more lime in the milk or curd from limed land than from unlimed land. The results showed such great variations from both the limed and unlimed land that no definite conclusion could be drawn therefrom. Bacteriological examinations of the milks and curds were equally negative in their results, which was to be expected, as the curd showed no more liability to taints from the limed land than from the unlimed. Hence, the only results actually obtained were a slightly increased acidity of the milk, probably accompanied with a slight increase in casein, and consequently a firmer and better curd.

"Considering how important it is to have a firm curd, and in view of the improvement in the herbage on the limed land, there can be no doubt that the liming was beneficial, and would have an effect lasting much longer than for the period of experiments. Moreover, the exceptionally dry season was not calculated to produce the best results which ordinarily accrue from liming. It also necessitates the removal of the cows from pasture to pasture frequently, so that the experiment came to a close at the end of May."

THE EFFECT OF CREAMERIES ON FARM VALUES.

A correspondent of the St. Paul (Minn.) *Pioneer Press* has been making an investigation of the effect of the establishing of creameries, on the value of farm lands in that state and records the result of his observations, as follows:

"While attending a meeting of the Meeker County Dairy Association at Grove City, the other day, I took occasion to make inquiry regarding the influence of the creamery business on the value of real estate, and learned that since the establishment of the first separator creamery, land has doubled its value. And instead of the bran all being shipped east, as was the case before the creameries were built, all the bran from the local mills is being purchased by the farmers, and in addition, from twenty to thirty carloads are shipped back to the local stations from the Twin Cities and sold to the patrons of the creameries. There has also been a marvelous increase in the amount ot merchandise shipped to the towns along the roads where creameries are located. Farmers contributing milk to creameries soon become well-to-do, and are liberal purchasers of household and farm supplies. They also, as a rule, pay cash for goods, which gives a healthy tone to the business interests of the local towns.

Experiments With Dairy Cows.

Prof. Brandt, of Germany, conducted three experiments with light and heavy dairy cows, each lasting four weeks, the second commencing seventy days after the close of the first, and the third a year after the beginning of the first. Thirty of the heaviest milkers in the herd were separated into lots of fifteen cows each, according to live weight. The cows were kept under similar conditions as to feed and care during the trial, none being bred after the beginning of the experiment. The average weight of the heavy cows was 1,205 pounds, and of light cows 979 pounds. The leading conclusions from the experiments are:

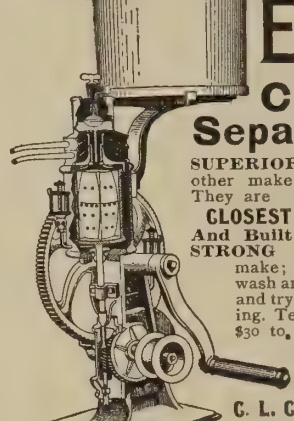
1. The milk of the small cows is richer in fat than that of the large ones.

2. Large cows eat a greater amount of feed than small cows; per thousand pounds live weight they eat less.

3. Small cows produce less milk than large cows, absolutely and relatively.

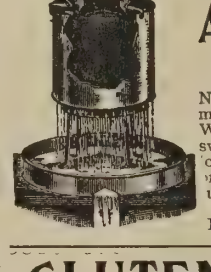
4. When in thin flesh, small cows may produce more per thousand pounds gross weight than large cows.

5. Large farrow cows are more persistent milkers; on the other hand small cows show a greater tendency to fatten on the same feed, with a decrease in the milk flow.



6. The loss in selling ten of the large cows amounted to five guilden per head on the average, after having been kept nearly a year, while the loss for ten small cows, was twelve guilden per head.—*Feeds and Feeding.*

THREE milk dealers in Kansas City, Mo., were recently arrested and fined $500 each; one for putting a preservative in his milk and the others for selling milk below the legal standard in butter fat.



Evidently the Kansas City judges propose there shall be no fooling with their milk supply.

4,000 Pounds
is the guaranteed capacity of this wagon. It is equipped with
ELECTRIC STEEL WHEELS
with stagger oval spokes, broad tires, etc. It has angle steel bounds front and rear. It's low down and easy to load. One man can load it; saves an extra hand in hauling corn fodder, etc. A pair of these wheels will make a new wagon out of your old one. Send for free catalogue and prices.

"SAVE THE BABY!"

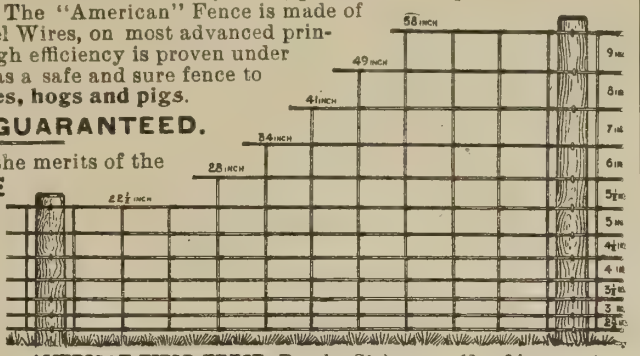
The first instinct of the mother-heart is to preserve her little one. Its life and health take precedence even over her own. The common dread which women who are looking forward to the coming of a new and precious baby into the world first feel, is that they may not themselves be able to go safely through the trying ordeal, and secondly comes the fear that the darling little baby's life or health or general well-being may somehow be sacrificed.

But there is no real need of apprehension in either direction. If any woman who is expecting to become a mother will follow the example of Mrs. Orrin Stiles, of Downing, Dunn Co., Wis., the most perfect confidence may be felt in the happy outcome of this critical period, both for the mother and the child.

"I have been intending to write to you ever since my baby was born," says Mrs. Stiles in an interesting letter to Dr. R. V. Pierce of Buffalo, N. Y., "in regard to what your 'Favorite Prescription' has done for me. I cannot praise it enough, for I have not been as well for five years as I now am. In July last I had a baby boy, weight 11 lbs. I was sick only a short time, and since I got up I have not had one sick day. I have not had any womb trouble since I got up. I was not only surprised myself but all of my friends here are surprised to see me so well."

The properties of this grand "Prescription" and what it has accomplished for thousands of women, are more fully described in one chapter of the People's Common Sense Medical Adviser by R. V. Pierce, M. D., a splendid thousand-page illustrated volume. It will be sent free paper-bound, for 21 one-cent stamps to pay the cost of mailing only; or, cloth-bound for 31 stamps.

The "Favorite Prescription" is entirely free from alcohol; unlike nearly all other proprietary medicines for women, which merely give a temporary stimulation and are likely to induce a morbid, unhealthy craving. The "Favorite Prescription" gives energy and nerve-tone that is real, healthy and permanent.



THE FENCE THAT FENCES.

"AMERICAN" ALL STEEL WOVEN WIRE FIELD FENCE.

Large, strong wires heavily galvanized. **Tension curve** at every intersection of main strands and stay wires, provides for expansion and contraction. The "American" Fence is made of Best Bessemer Steel Wires, on most advanced principles. THE NEW BOOK Feeds and Feeding

By Prof. W. A. HENRY,

Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

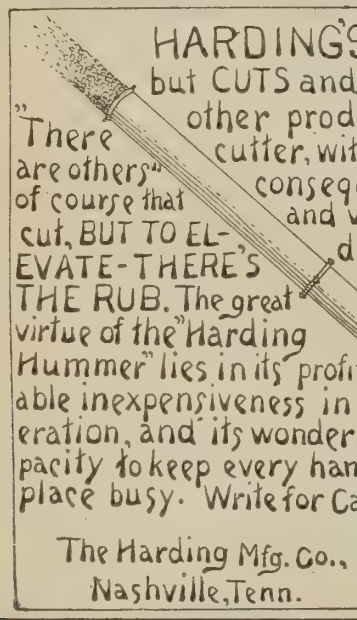
SMALLEY MFG. COMPANY, Sole Makers, MANITOWOC, WIS.

MAKE ONLY **SWEET ENSILAGE**

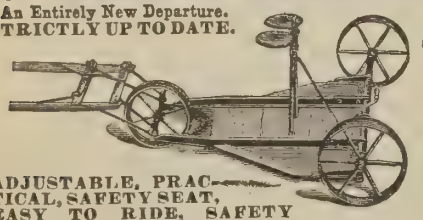


Ever since the ensilage system has been introduced in this country it has been the ambition and effort of siloists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste.

The best way to Shred Ensilage is with the

St. Albans Ensilage and Fodder Shredder.

It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail free a pamphlet on the subject.



ST. ALBANS FOUNDRY CO., ST. ALBANS, VT.

DAIN THE BEST. THE CHEAPEST. THE STRONGEST. THE MOST DURABLE **STEEL CORN CUTTER.**

A PRONOUNCED SUCCESS---THE VERDICT IS UNANIMOUS.

There Can Be No Question

About the merits of a machine which will elicit such endorsement as that contained in this letter. It will only cost a postage stamp to interview Mr. Evans further. If you need a new separator—and you surely do if you have not a Tubular—it will pay you to know the truth from him. Read it and then write him.

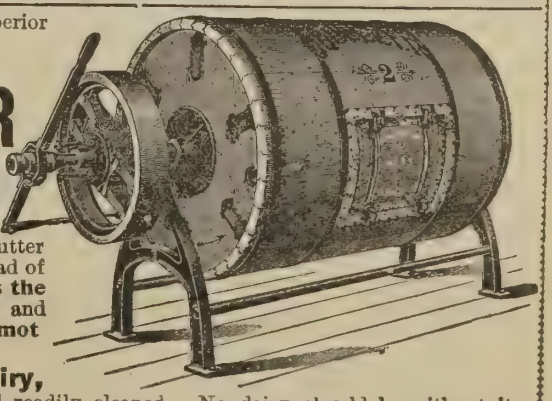
THE SHARPLES CO., Chicago, Illinois.
WHITTEN, IOWA, June 30, 1899.

Gentlemen:—I have your favor of June 28th, in which you ask how the Tubular suits me by this time, and wish to say,—the better I become acquainted with the Tubular, the better I like it, and I am fully convinced that it is far superior to any separator I have ever seen. I used to think the Alpha was a pretty good machine, and do yet for that matter, but the Tubular beats it in every point of the game.

While I was running the Tubular in the contest with the new Alpha, placed in my factory for that purpose, the Tubular beat the Alpha on clean skimming, the temperature running from 62 degrees to 80 degrees. The Tubular skimmed just as good at one temperature as another. At different times I skimmed as high as 2800 pounds of milk per hour, and showed a test of .03% butter fat.

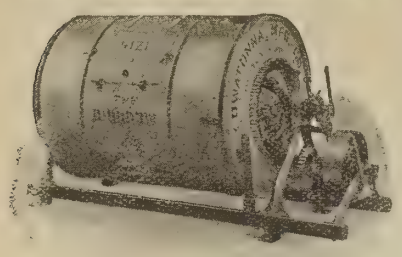
The Alpha man made an awful kick when I told him I was going to take the Tubular. I hated to let him down, but the tests were against his machine, and I could do nothing else under my agreement that I would take the machine that did the best work. He said he would sell me the Alpha "right" if I would throw out the Tubular, but I did not ask him what he meant by "right," and am very well pleased that I did not, as I am even better pleased with the Tubular today than I was when the time came to make a choice between that and the Alpha.

If you have any customers in doubt about the Tubular being a first-class machine, I should be pleased to have you send them here and I will show them a machine doing the finest work ever done by a separator. Very respectfully yours,
B. J. EVANS.



THE SHARPLES TUBULAR SEPARATOR

Represents the latest great advance in separator construction. More revolutions, less speed, more centrifugal force, less power, more perfect cream, less fat in skim milk, more durability and less complication. The bowl alone revolves. It is a hollow steel. It spins on air.



Send for Catalogue No. 46.

ALDERNEY BUTTER COLOR
Gives **Natural June Tint.** Butter colored with it will retain its color when put in cold storage. Try it and be convinced.
Manufactured by THE HELLER & MERZ CO., Office, 55 Maiden Lane, N. Y.
BRANCHES:—Chicago, 14 No. Clark St.; Boston, 98 Commercial St.; Philadelphia, 109 South 2nd St.

The Machine that will Build a Butter Trade.
Because it will make a superior quality of butter.
THE **SQUEEZER** COMBINED **CHURN AND WORKER**

squeezes the water and butter milk out of the butter instead of grinding it. **It preserves the grain,** distributes the salt and color evenly and **prevents mottles.** It is
Made for the Dairy,
and is easily operated and readily cleaned. No dairy should be without it.
Will do Exhaustive Churning at any Temperature.
We are prepared to repair all cream separators and employ highly skilled men for this work.
Write for Catalogue No. 82. **ELGIN MANUFACTURING CO., ELGIN, ILL.**

DISBROW

The Original Combined Churn and Butter Worker

Churns and works the butter on the only true principle. Brings the butter to the working rollers no faster than the rollers can take care of it without rubbing the butter. No solid BALL of butter comes in contact with the rolls to be scraped to pieces by the rolls and made salvy. It is the only combined machine in which butter has been made that scored 100 points.

The manufacturers have never made any claims for it that were not fully proven by actual tests of the machine.

The Disbrow tells its own story and a fair trial is all that is needed to prove its merits.

THE DAIRY "VICTOR" Churn.

This Combined Churn and Butter Worker is proving itself to be precisely what the farmers and dairymen have been seeking after. It's work is as complete as the work of the "Factory" Victor Churn, which is rapidly supplanting every other Combined Churn and Butter Worker.

IT IS THE ONLY SUCCESSFUL DAIRY COMBINED CHURN AND BUTTER WORKER ON THE MARKET.

It is easy to handle, easy to clean, perfect in its work, durable and reliable. It charms every farmer and dairyman who sees it work. Manufactured by . . .

F. B. FARGO & CO., Lake Mills, Wis.

Put Your Nose Over It.

Pull the lid off a can of milk at any shipping or delivery station and put your nose over it. Smells badly doesn't it? Do you know why? It is because the milk was not properly treated. If it had passed through a

PERFECTION MILK COOLER AND AERATOR

it would **smell sweet, be sweet** and **remain sweet.** It takes out all animal heat and with it all bad odors of **animal, stable** or **food.** Milk so treated makes perfect butter and is perfect for household use. Made in sizes from 1 to 200 cows. Send for free illustrated catalogue and prices on **Farm and Dairy Supplies.**

L. R. Lewis Mfr., Box 10, Cortland, N. Y.

Put Your Mark

on the butter you sell. The handsomest prints are made on the Rapp Automatic Butter Printer. The very best machine ever made for the purpose. Handiest, most rapid working, easiest adjusted printer ever made. Write for large illustrated catalog, containing full description of the

RAPP AUTOMATIC Butter Printer

and of a hundred and one things needed in every dairy—cream separators, milk strainers and coolers, automatic milk scales and butter tools. Mailed free

J. CHRISTIAN HAY writes an interesting communication, to the *Creamery Gazette*, on "Rational Methods of Milking," in which he says:

"There are at present 16,000,000 milch cows in the United States, and the average yield from each animal is 4,000 lbs."

It is difficult to conceive of the source from which Mr. Hay derived his judgment as to the average yield per cow. He will find, if he investigates, that it is less than 3,000 lbs. An investigation of 10,000 cows, in one of the best dairy districts of Wisconsin by us, a few years ago, gave only about 3,500 pounds per cow. It would be a good idea if Mr. Hay, or some other enterprising Iowa dairy writer, would take a dozen or so of the average Iowa creameries, and make a careful investigation of each as to the number of cows each patron has milked for the year, and the number of pounds of milk derived per cow. The creamery would furnish the average test of butter fat.

We think the disclosure would emphasize the contention HOARD'S DAIRYMAN is constantly making against the poor cow, and the still poorer ideas concerning cows and cow management, which, unfortunately, are too prevalent everywhere.

HOW NOT TO SEE IT?

It is astonishing how easy it is for people to talk around a question, and not see the real objective or central point. The editor of an Iowa paper is an example. In writing about the creameries of that state, he says:

"While the writer knows but little about the business, he is at a loss to know wherein the creamery is especially beneficial to the dairyman and farmer. From figures at hand he believes the average price realized for milk, when it or the cream is sold to the creamery, is about a half cent per quart, or possibly a trifle over. Now, while his knowledge may not be very broad regarding the lacteal product of the bovine, he believes that a cow which averages a product of twelve quarts of milk per day the year round, is considered an excellent animal. This figured in dollars and cents, is six cents, or a trifle more, per day, for investment, feed and labor connected with one animal, which is far from enough to make the dairy a paying thing when milk is sold to a creamery. Of course there are exceptions, and one is in the instance of a co-operative creamery, where the dairymen own an interest in the business, and get a share of the profits from it. In this way, the creamery may be made to pay the farmer and stockholder handsomely, but it cannot be made to pay him in any other way. It is not meant by this that farmers should stop producing milk, but that they should either own the creameries themselves, or find a way of getting more for their milk than the average price received the year round by them."

The editor did see that the prices obtained left no profit to the patrons. But he has fearfully overdrawn the capacity of the average Iowa cow, in allowing that the milk yield is twelve quarts of milk a day for the season, for, say, 300 days, or a total of 7,227 pounds, when not fifty per cent of the cows of that state yield even four thousand pounds a year. Then again his eye is all on the creamery, as if that is the gauge of success; that it is taking from him money once rightfully earned. So he recommends the co-operative creamery as a remedy.

But still the cause of the low revenue to the farmer is not touched. It is the poor, unfit cow that stands in the way; bred by a man who has false ideas of what shall constitute a profitable dairy cow; handled still from wrong ideas. Can the creamery change the cow, or the low, false estimate the farmer has of cows? No! The place to make profit from cows is at the farm end of the business. The tax the creamery imposes is but a mere trifle compared with the combined tax of ignorance of dairy questions on the part of the patron, and the poverty stricken character of the cows he keeps.

The "demnition grind" of events will soon squeeze a little legitimate thinking into the patrons of these creameries, not only in Iowa, but all over the land. Keeping poor cows, with poorer ideas of dairy management, and then charging it all up to the creamery is simply to reason and act like children. When these patrons come to think that it pays to know something by the head as well as by the hand, and go to work to study their business as all other successful men have to, then they will begin to make a profit.

FEED.—CONDITION OF THE FOOD.—ENVIRONMENT AND THE COW.

There has ever been, and no doubt there ever will be, a proneness on the part of men to theorize and speculate. It is the foundation of all investigation. But it seems to be carried too far very much of the time. For instance, there is a class of theorists, called vegetarians, who declare that man is a herbivorous animal, and therefore should eat no flesh or animal food. But nature seems to have a way of her own that is very disrespectful to this class of theorists. She starts all infant life on animal food. Milk is an animal food. The birds that eat seeds only, feed their young on worms, larvæ, etc. Recent food experiments have shown that vegetable protein has not near as great potentiality in digestion as has animal protein.

Darwin was one of the first investigators who gathered the facts first and theorized as to their meaning afterward. On this great question of feeding for the production of milk we need more Darwins, men who study keenly and closely the effect of various foods, for the love of knowledge, as he did, as well as for the sake of money. Then, besides, we ought to study just as keenly and wisely what are the conditions of food which modify its feeding effect. Then again, what are the modifying effects of environment. Take these two things, the condition of the food and environment. The farmer who cuts overripe hay, corn stalks, millet or any other roughage, has not learned his lesson. He does not produce the stalk or the grain, nature does that, but he is responsible for the right condition of that stalk or kernel, so that it may produce the most milk possible.

Then again, he is responsible for the environment of the cow, which means the comfort, healthfulness, cleanliness, and temperature of her stable, and the character and temperature of the water she drinks.

All these things modify the good or profitable effect of the feed. The cow is in our hands. She cannot help herself. She cannot change her bad, unfavorable conditions or the wrong condition of her food. The owner must do that, or else he wastes his costly food.

Then, lastly, comes the character of the cow to which we feed this food. Was she rightly organized (that is, was she rightly bred) to take *good* food, in the right environment, and turn out the best profit possible? Was she rightly handled from birth, to make the most of her well organized motherhood, or has she been spoiled by ignorance of right handling?

For the breeding and handling of the cow, the farmer is again responsible. All these things modify, help or hinder the effect of the food we give the cow. There is a field here rich in both knowledge and money for every dairy farmer to study. The fearful waste of hard earned food that is going on, tells the story.

The surprising difference in the profit, per cow, as between one man and another, tells the story. The thousands of farmers who have spent a life of hard toil, with but little reward tell the story. Their wives and children know the story only too well.

Is it not full time for every owner of cows to say to himself: "*This thing of keeping cows without giving myself right knowledge and understanding on the subject has gone on long enough. I can see by the profit some other men get that knowledge pays. Henceforth for me and my household, we will make a better study of the cow, her environment, her feed and the right condition of that feed.*"

"Heaven helps those who help themselves." That is the true meaning of "good luck."

SOME GOOD THOUGHTS ON BREEDING.

The more a man studies this question of breeding farm animals for a distinct, *profitable* purpose, the more does he see two things clearly: (1.) That he is entering a domain full of mystery and uncertainty—the domain and mystery of life and reproduction; that, study as hard and long as he can, there is yet a vast deal to be learned beyond him.

(2.) That the great majority of the farm animals that are bred are the result of but little sound, clear physiological thought and reasoning from sound principles to legitimate results.

The following excellent article appeared in the *Maine Farmer* for September 15, of last year.

There is wisdom and sound conclusion in what Mr. Gifford says concerning the "ideal" that should be in every man's mind when he sets out to produce a good cow. It takes thought, study and right observation to have such an ideal.

A recent article in the *Maine Farmer* on the above subject attracted my attention and set me to thinking of the experience we have had at Devonshire Farm. The aim of every farmer should be improvement. God gave man the supremacy over nature, and has taught him some of her fundamental truths, so that he may change, modify and beautify all that is about him. But go contrary to these fundamental laws, and disaster is as certain as it is that night shall follow day. And yet there is hardly an ideal that the heart of man can conceive, but is possible of attaining with a certain measure of success. The thought is but the father of the result. And when Booth and Bates set to thinking of ideals in Short-horn breeding, the results were as certain as though the animals stood before them in flesh and blood.

Let the farmer first form his ideal, and then bend every energy to reach it. In the breeding of animals his first aim should be the sire. We have spent nearly as much money in searching for an animal to head our herd as we were obliged to pay for him. But when the animal was found which came nearest the ideal, nothing could deter us from the purchase. It is breeding up to a standard, never allowing an inferior sire to step into the herd, that is wanted on every farm in our country.

Even if the bull as an individual is almost perfect, he should never be chosen unless back of him are individuals of equally good characteristics. When we chose the last bull, we selected him not only because of his individual qualities, but because we saw in his dam an animal which approached to a remarkable degree the standard we had set. And we traced his pedigree back through remarkable animals on both sides until we had reached one of the best animals in the herd of Queen Victoria.

It is generation after generation of careful breeding, and that alone, that fixes any desired qualities. A bull should always be chosen to improve the herd. When a change is desired to avoid too close inbreeding, never take a backward step, but search until the animal is found which will make more certain the results already attained. The bull is half the herd; and if half of some of the herds of New England were weeded out by careful selection, and the proceeds invested in sires which would improve with certainty, there would be a great deal more profit for the farmers.

I started to tell something of our own experience, so I wish to state the results we have reached. The calves which have been dropped the past year are as fine as we have seen anywhere, and give promise of coming nearer, than anything we have before bred, to the ideals we have before us. But no farmer should have an ideal that he can reach until he steps just beyond the shadow, and so we can see the line for improvement, and when the time comes to change we shall search until we find. If the animal is not found which is desired, the careful breeder may, by judicious selection on both sides, be able to breed for himself the animal which is to improve his herd. The principal thought which I wish to leave with your readers is that if they will only have a standard, an ideal toward which they are working, and will then follow the underlying laws and principles, year after year, they will see the work grow better and better, with the certain hope of the crowning finish.

J. E. GIFFORD.

Devonshire Farm, Sutton, Mass.

Mr. Gifford's ideal may not be that of the breeder of the ideal dairy cow, but whatever it is, he can never achieve success if he does not follow it out clearly and truthfully.

What is Cow Manure Worth?

If all the liquid and solid excrement of a cow is saved, it will make, with enough straw to absorb it, about a two-horse load per month—such as farmers usually draw from stables and barnyards to the fields. This manure is already on the farm, and it ought, therefore, to be worth more than in a city or village stable, where it has to be drawn several miles before it can be applied to the land. On the other hand, the farmer who draws manure from a city, fixes up a wagon box that will hold fully twice as much as any load of produce that he takes from the farm to the market. A dollar a load is the usual price paid for these large loads, when contracted for by the year. In the summer, when manure piles in the city are a nuisance, manure from cow stables will be sold much less than this. We have known it offered at fifty cents a load, and in extreme cases have seen it given, free of cost, to whoever will take it away.

Market gardeners, who buy most of the manure from city stables, say that these large loads are necessary, for the manure is unfermented. By the time it is rotted down and ready to apply to the land, its bulk is reduced fully one-half. They do not like manure from cow stables, so well as that from horses. It is slower to heat, and contains less phosphate and nitrogen, than the average manure from horses. This is partly, perhaps, because oats are the common grain food of horses, but are less frequently fed to cows. Besides, when a cow is giving milk she puts more of the nitrogen into the milk pail than the horses use. But when cows are fed clover hay, while the horse has timothy, and the cow has, besides, a ration of wheat bran daily, her excrement will be nearly, or quite as good as that from a horse. The whole question about the value of different kinds of manure, depends more on the feed than on the stock. A first-rate cow, with a good digestion, able to eat heartily, and fed some linseed meal with wheat bran and clover hay, will make manure that will be worth three times as much per load, as that from a cow that is fed mainly on straw.

We often see statements in farm papers, that the manure from a cow per year is worth nearly or quite as much as her dairy product when made into butter. But it must be a very poor cow, indeed, or one fed extravagantly, of which this can be said. Much of the manure of a cow that is at pasture, is scattered in the fields, and as it ferments, it is wasted in the air, doing very little good to the land whereon it falls. Instead of its being worth $40 to $45 a year, $20 would be a liberal estimate for it. In most cases the addition of five dollars worth of phosphate, and the same of potash, would more than double its effective value. This, however, will not be needed where the cow, in addition to her other feed, has had grain or meal that is rich in both nitrogenous and mineral plant food.—*American Cultivator.*

OUT of 423 cows, furnishing milk to the Syracuse, N. Y. market, only 4% were found affected with tuberculosis.

THE Co-operative Creamery at West Saem, Wis., is one of the largest in the state. The value of its annual output of butter is over $100,000.

THERE was not space enough on the preceeding page for the illustrations which accompany the review of Bulletin 75 of the Wisconsin Experiment Station, and, as it seemed expedient to place them where they could all be seen at once and thus more conveniently compared one with another, they are given on pages 494 and 495.

THE Dairy and Food Commission of Michigan publishes a monthly report, and thus gives the people of that state early information of all its doings. This is a practice that might be followed in other states with most excellent results.

The June report of that Commission shows 116 dairies inspected and gives the condition in which they were found under the different specifications of condition of cows, stables, yards, water and general surroundings, and whether good, fairly good, poor or bad. It also shows that 161 samples of food products were analyzed, of which ninety-four were found to be pure and sixty-seven adulterated. In the latter class were six samples of what was represented to be butter, taken from hotels in Saginaw and Lansing, that proved to be oleomargarine, and not a bad argument for passing the law to tax colored oleomargarine ten cents per pound.

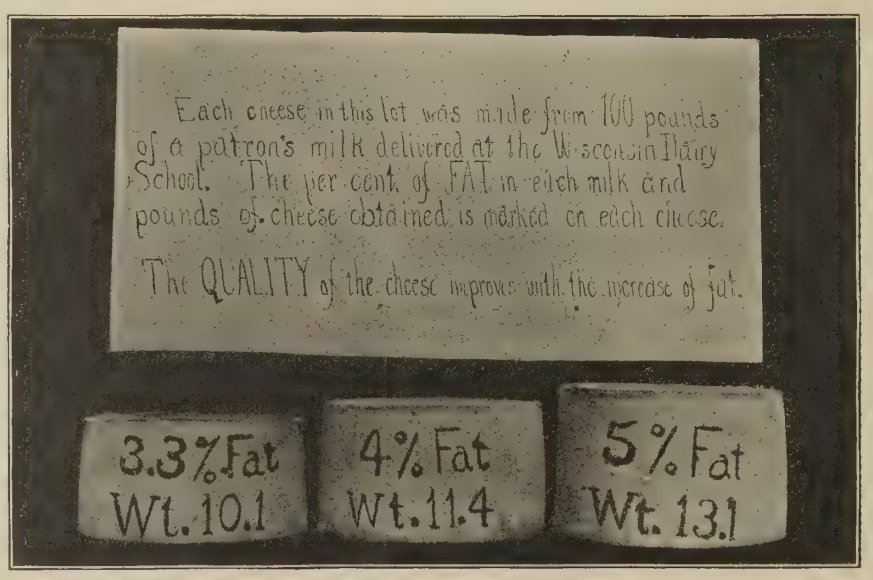
TUBERCULOSIS AND MILK.

A sample copy of HOARD'S DAIRYMAN fell into the hands of a gentleman in Rhode Island, who forthwith sent us his subscription for a year. The next day, having read a little more in the paper, he remits $2.00 for a copy of Prof. Henry's book, "Feeds and Feeding," and submits the following inquiry:

On page 460 of the sample copy just sent me, there is an article, "Tuberculosis and Milk," with the spirit of which I wonder if you agree? I must say that the argument does not strike me with any force at all. "One swallow does not make a summer."

There was very little "spirit" in the article referred to, as it was merely a report of the facts developed at the New Jersey Agricultural Experiment Station, with a herd of cattle, which had responded to the tuberculin test. It was stated that "the milk from these cows has been tested and analyzed again and again, and thus far no germs had been found in it. So far as science could determine, these cows produced clean and healthful milk." It was said further, and out of abundant caution, that it was not safe to conclude that the milk had never contained any germs, for they might have been present on occasions when the milk was not tested.

It was somewhat reassuring, however, to know that these germs were not numerous or frequent, even if they did sometimes exist.



These facts, taken in connection with the further facts, that it never has been proven that any case of tuberculosis in man resulted from the use of milk, that with an increasing consumption of milk, there is a decreasing per cent of human tuberculosis, that there are many families that have unwittingly used milk from cows, that were afterwards known to have been tuberculous, and are none the worse for it—facts like these, we are forced to admit, lead to the conclusion that the danger of tuberculous infection from milk is at least exceedingly remote, and not to be compared with the dangers, from other sources, that are about us on every hand.

There is danger in traveling on boats, in cars or wagons, or even in journeying afoot, and yet people are not deterred from going about on business and for pleasure. The great majority of travelers reach their destination without mishap, but there are occasional accidents, resulting in more or less serous disability and death. Shall we all hereafter stay at home? The man who makes it his special aim in life to collect and preserve the records of disasters, and is always ready with "statistics" to prove that the world and all its people are doomed to early destruction, is anything but a philanthropist. HOARD'S DAIRYMAN does not agree with the "spirit" exhibited by such men, and is not at all in sympathy with the "spirit" of any other man or class of men, who are constantly striving to magnify the possible dangers that many inhere in the milk of one cow in a hundred, and extend them to the milk of all cows. In other words, HOARD'S DAIRYMAN strives to confine itself to the facts in this matter, and cheerfully admits that it takes more pleasure in recording the evidence which tends to show the innocuousness of milk and all other food products, that in repeating the much-worn reports to the contrary.

THE RELATION OF FAT IN THE MILK TO CHEESE IN THE HOOP.

It is no more certain that twice two is four than that four per cent milk will make more cheese than three per cent milk. This is not theory, but fact, demonstrable both by figures and experiment. Prof. Decker shows it in his communication and the accompaning illustration on this page.

One hundred pounds of four per cent milk contains one pound more fat than 100 lbs. of the three per cent milk, and any cheese maker, worthy of holding his job, can put that extra pound of fat into the cheese, and with it a due proportion of water. There is in cheese approximately half as much water as fat and casein combined. The fat will carry its share of this water and it is therefore not unreasonable to expect that the pound of fat will increase the weight of the cheese by nearly one pound and eight ounces, and with cheese at eight cents per pound, four per cent milk should be worth at least twelve cents per hundred more than three per cent milk, even when we ignore the better quality of the cheese and the proportional increase of casein with the increase of fat.

Here are the figures:

100 lbs. 3.3% milk yields	10.1 lbs.	cheese
100 lbs. 4.0% "	11.4	"
Therefore:—		
0.7 lbs. fat yields	1.3	"
Again:		
100 lbs. 4% milk yields	11.4 lbs.	cheese
100 lbs. 5% "	13.1	"
Therefore:—		
1 lb. fat yields	1.7	"

The Babcock Test for Cheese Factories.

The Facts Stated and Illustrated.

ED. HOARD'S DAIRYMAN:— The method of dividing the money for milk at cheese factories, according to butter fat test, is slowly but surely gaining ground in Wisconsin. In the southwestern counties of the state, it is the exception to find a cheddar factory that is not paying by test.

Two or three years ago, in Kewaunee county, the factories were paying according to the old pound-for-ten system. I recently took a trip through there on my bicycle, and when I would stop at a factory and ask if they paid for milk by test, the answer would be, "you bet we do."

There is, however, a district around Hilbert Junction where the pound-for-ten system has its grip on the factories. One factory does it that way because the next one does. When asked why they do not pay by test the reply is, that "someone" has said, that no more cheese can be made from 5% milk than from 3 % milk, and they believe it, and do not try to locate the authority for the statement.

Last winter at the Dairy School, I had students prepare milks with skim milk and cream containing 0%, 1%, 2%, 3%, 4% and 5% fat. The DAIRYMAN in one of its issues, had a photograph of these cheese, and I find that it has set some farmers to thinking. I send you herewith, a photograph of a series of cheese made—not from milks prepared from skim milk and cream, but from patrons' milks selected according to butter fat. Each cheese was made from one hundred pounds of milk, and the weight of green cheese obtained is marked on the cheese. It must be remembered that these weights are for green cheese, just as it came from the press, made for a home trade; that the cheese weighing 10.1 pounds cured out to 9.5 pounds; and that the relation between the different cheeses is the point to be borne in mind.

The five per cent milk did not make fifty per cent more cheese than the 3.3% milk, as some people think it should in order to justify paying by the test. They overlook the factor of quality. The five per cent milk contains more butter fat, both actually and in proportion to the casein, and because of the latter fact, makes a cheese of finer quality.

Secretary Wilson states, that when he wanted to get cheese of exceptional quality for export, he had to pay a higher price, and that this higher price was proportioned to the amount of butter fat in the cheese.

If one will examine the market quotations for cheese, he will find that the price of "full cream" stands first, "light skims" are a little lower, "half skims" lower still, and "full skims" very low. Dr. Babcock has shown, in the Eleventh Annual Report of the Wisconsin Experiment Station, that, if the prices of such qualities of cheese are applied to the yields per one hundred pounds of the several qualities of milk, the results will be the same price per pound for butter fat. It is, therefore, the fat in the milk, that measures or determines its value for cheese.

If we take the fat all out, and make cheese from the skim milk, it will have no real market value. If a fisherman can be found, who wants a "big lot" of fish bait for his money, he may pay one cent a pound for it, but one cent a pound on a yield of five and a half pounds of such cheese from one hundred pounds of skim milk, is but five and a half cents, which will not pay for the labor, fuel, color, rennet, salt, bandage, box, cartage and freight put into it, and it would pay much better to throw the good skim milk away than to charge up damages against it in this way.

Let the patron who thinks that he ought to get extra pay for his other milk solids, take this into consideration. It is the butter fat that counts.

CONCLUSION.

Are you delivering milk to a cheese factory? Do they pay for your milk on the pound-for-ten system, or any other system than by butter fat content? If so, you are either receiving more than rightfully belongs to you, which is not consistent with honor, or less than rightfully belongs to you, which is not consistent with sound business judgment.

JOHN W. DECKER.

THE TUBERCULOSIS SCARE.

It is a pleasure to find that there is here and there, a scientific man competent to write on this question, who does not think it necessary to add to the present tuberculosis scare, by means of exaggerations couched in scientific terms.

Professor Wrightson writes as follows in the English *Agricultural Gazette*:

"The pleasure of dairy farming has been somewhat marred by the idea of unsoundness in so large a proportion of our cows. It is to be hoped that ere long our knowledge will at least be sounder than it appears to be, and probably our cows are sounder than our knowledge. The seeds of disease, alas! are sown broadcast, even in the fairest scenes, but no human measure can eradicate them. There is such a thing as knowing too much, and life would not be worth living if we could see the approach of disease and death. If is well, no doubt, to eliminate, as far as possible, all predisposing causes, but to detect, in a manner which may be termed prophetic, the germs of a disease which has not declared itself, and which may remain latent until death intervenes from totally different causes, is going a step too far. If an animal

is diseased, by all means isolate it or destroy it; but to do so because an animal reacts to a reagent and thereby exhibits a tendency, is, I repeat, going a step too far. All animals have this tendency, for it is evident that although an animal does not react to-day it may react to-morrow, or at least shortly. The test to be effective should be constantly used. A cow free this summer may not be so in the autumn, and hence a system of monthly testing would be necessary.

"Animal food, bacon, cheese, butter, cream and milk have always been regarded as wholesome foods, and they are as wholesome now as ever. Why should we terrify ourselves with wondering whether animals used as foods, or their products used as food, may have the seeds of disease or death in their bodies (which must be the case) when they are apparently healthy, thriving or yielding large quantities of good milk? As well might we question the wholesomeness of hares, rabbits and poultry, and have every chicken subjected to a tuberculin test before we wring its neck. To such preposterous lengths might we be led but for the strong common sense which happily rules. I trust, therefore, that the scare which has lately prevailed will soon be moderated, and that attention will be fixed upon animals which are diseased, and not on those which exhibit tendencies or liabilities to disease. As well might a crusade be set on foot against the salads, raw fruit, oysters, or any other food of like description which must be exposed to the invasion of germs. They are absolutely everywhere. In water, in air, in all crowded assemblages of people, they positively reek. In all railway carriages they abound, and in cabs they are ubiquitous. They are in the cow-house and in the kitchen. They must be in every breath inhaled, and yet we live. Too much has been made of the germ, simply because we have only lately discovered that he is universal."

Variations in the Test of Milk.

The daily tests of the milk show to what extremes the milk of one cow will vary from day to day, a difference of one-half of one per cent, and occasionally even more than one per cent being noticed on some days.

This is shown by these records for August, November, December and June. Such variations, however, tend to equalize each other from day to day, and milk of unusual richness is generally followed by exceptionally thin milk, so that the average richness of the two lots comes near to the normal quality that the cow produces. This daily variation in milk is much more striking in some cows than in others, even in a herd having the same feed and care; it seems to depend largely on the health and more or less excitable temperament of a cow. Nervous cows showing a much greater tendency to unevenness in the quality of their milk than cows of a quiet disposition.—*Wisconsin Bulletin No. 75.*

A Connecticut Silo Experience.

ED. HOAD'S DAIYMAN:—In 1889 we built a square silo 15×15 feet and 20 feet deep on to the gable end of our basement barn, covering it with a tin lean-to roof. The tinning lean-to bill was $19.00 Except framing we did the carpenter work ourselves; the total outlay being about $100. We used six-inch chestnut girts and boarded up and down outside and inside with four inch pine with paper between. Only one thickness of boards on the inside. It has been a success, although the silage has wasted somewhat on the outside. It has been filled every season since with an extra partial filling of oats and peas July 1st for several seasons. After about five years use the lining rotted through in the lower part and we put building paper over and relined with rough through and through hemlock boards which swelled tight in filling. This is as cheap and satisfactory a way of repairing a square silo as I know of. In 1898, rats and decay having ravaged the bottom lining and timbers we cut out the inside lining up to the second girt and filled in with brick and grout backing against the outside boards. This year as the lining shows wear further up will paper-hang the whole inside with tarred paper. Some one may object to a silo that needs so much patching, but it is the ultimate necessity of any of the board lined ones to be patched or torn out. Tarred paper is cheap and I believe will be effective. This silo has bulged and corner irons have been necessary to prevent bursting. The corners had 6×2 tenons into corner posts with two pins, but a stronger corner tie is necessary to stand the strain. Our corners inside have four inch stick split cornerwise and nailed up and down, but it were much better to tie the grits with an eighteen inch or two foot stick and ceil upon it. This would be stronger and fill out the corner better.

CARRIERS.

The thorn in the flesh of our silo outfit is the carrier driven by sprocket at the bottom. It will catch and break and double up, stop all operations, spoil the temper and raise confusion generally. There seems to be some defect in driving from the bottom and pushing the load up the slide. You can push with a stick or a rod, but a chain is made to pull with and if asked to push will buckle sometimes. I wonder if others are troubled in this way. It is a well made carrier. The defect seems to be a defect of principle. E. C. BIRGE.

Southport, Conn.

Ripening Cheese at Different Temperatures.

The results of some valuable experiments on the above subject are reported by Prof. Dean, in the twenty-fourth annual report of the Ontario Agricultural College. Details of how the experiments were conducted need not here be given, but the following are the conclusions which were arrived at by the experimenters:

1. The cheese lost considerably more during one month's curing when kept at a comparatively high temperature. This was true for each month during the experiments, and also for the season. The average per cent of shrinkage during the season for one month in cheese weighing about thirty pounds, cured at 60° F., was 3.40%; cheese cured at 66° F. lost 3.85% in weight, and cheese cured at 69° F. lost 4.31%.

2. The quality of the cheese was very much better by curing at 60° F. The average score for the season for cheese made in the College dairy was nearly three points in favor of cheese cured at 60° F., as compared with similar cheese (from the same vat) cured at 66° F., and five points higher compared with those cured at 69° F. The difference was more marked still, in September and October cheese. The flavor was very much better in the cheese cured at 60° F. and the texture was a marked improvement. Cheese cured at a high temperature go off in flavor quickly, and have a sandy or mealy texture. The cheese made in October, and cured at 60° F., were considered to be worth from ½c to 1c per pound more than similar cheese cured at 70 to 75° F. Cheese cured at the lower temperature have a very much better keeping quality.

THE use of formalin, as reported by Mr. Wheaton on page 491 for preventing mold in the curing room, appears to us to be fraught with more or less danger—not immediate perhaps in very great degree, but certainly is a letting down of the bars, for pernicious practices to come in. It is but a short step from using formalin as a spray to using it or some other germicide in the curd or milk. Dairy products, we insist, should be—the simile is as apt as it is old—like Caesar's wife, above suspicion.

Cheese will not mold in a proper curing room. If the cheese molds, the evidence is conclusive that the curing room is defective and needs remodeling. Remove the cause and the disease will abate.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS		
	Protein.	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12 to 15.0	0.5 to 0.8

TWO STORY STABLES.

I am going to build my cow barn over this fall and would like to put my horse stable over the cows, (cows being in basement, built of wood), if it would be satisfactory. L. G. R.

Saratoga Co., N. Y.

We have seen arrangements of this kind that were very satisfactory, but in general, too little care and expense are given to making the upper floor water proof. It can be done, and must be done. Otherwise the whole business becomes a nuisance.

CLOVER SILAGE FOR SUMMER FEEDING.

I am thinking strongly of building a stave silo for summer feeding to be filled with clover. Should the clover be cut into the silo same as corn, and what amount would it be safe to figure for twenty cows for the summer with what pasture they could get. I know this is a very indefinite question, but would like some idea; would rather put up too much than too little. L. G. R.

Saratoga Co., N. Y.

The clover should be cut, as this will let it pack closer and be more convenient for feeding. This is not to say that it cannot be put in whole, for in fact we have seen excellent silage made from whole clover.

You may need from twenty to sixty pounds of silage per day for each animal for a period not likely to be less than six weeks.

At forty pounds per day, the total would be eighteen tons, but, as you say, it would be advisable to put up much more than this. Build the silo not less than twelve feet in diameter and twenty feet high, and when the corn is ready, fill it in over the unexpended clover.

WHITE BUTTER JARS.

There has a question arisen here in regard to white butter jars. I asked my grocer to-day to get me some, and he asked a potteryman, one, by the way, that makes brown jars, and he made the statement that the State Board of Health had forbidden the making of white jars in the state, and was going to prohibit their sale and use on the grounds of using sugar of lead in the glazing, which the salt in the butter dissolved. Is there any basis for this claim? I greatly prefer, and my customers also prefer, the white jar.

Fortsville, N. Y. L. G. R.

We cannot say as to whether any such law has been passed in New York, but should consider it very unlikely, as there is no reason why white butter jars should be any more dangerous than any other color. Lead glaze can be, and is used on different kinds of earthen ware, colored as well as white.

There may be a law forbidding the use of a lead glaze on all earthenware, which would be an excellent regulation, but this would not prevent our correspondent from buying all the white butter jars he needs, and have them free from any lead glaze.

ELEVATING SILAGE.

I want to know if there is any way to elevate ensilage into twenty-four foot silo without buying a carrier? I do not need an angle or swivel carrier, necessarily, as the ensilage would go straight up and in silo. Please advise and ask your readers to advise me. Can I get ten-inch-cut shredder and two horse tread-power and fill silo successfully? Readers who know, please advise.

Osceola, Ark. W. A. J.

See the advertisements on page 504 and write to the manufacturers and dealers. Of course, silage could be hauled up in buckets or immense sacks with hay fork tackle, but it would be more expensive in the end.

TIGHTENING THE HOOPS ON A STAVE SILO.

I would like to know what has been the observation or experience in tightening up a stave silo. My silo is 14 feet in diameter, 24 feet high, and built out of pine pieces, 2×6×24, dressed all sides, not beveled. There are ten hoops made out of ⅝ iron rods divided into two sections, each one-half the circumference of the silo, the ends fastened in a 4×4×24 piece which acts as a stave also. When I built the silo last fall, I had the hoops drawn around the silo as tight as one man could with a fifteen-inch-long wrench, then filled it with corn ensilage, which kept almost perfect.

Since my silo has been emptied, the staves have shrunk so that the hoops drop down 9 to 12 inches in the center of each section. The question with me is, how much slack must I take up? W. S. B.

Cha-tanooga, Tenn.

We doubt whether any one can give explicit directions in a case like the above. We should say, make the hoops fairly "taut" at first, and then loosen them from time to time as may be necessary to accommodate the swelling of the staves.

VOLUNTEER RYE IN OATS.

I have a piece of land that was in rye last winter, grazed down this spring and summer, but some of the rye was not eaten and ripened seed. I wish to plant this in winter grazing oats to thresh when ripe and grind for Jersey cow feed. Will the rye that may grow and come in the oats do any harm to the cows or affect their milk? W.

Nashville, Tenn.

The rye will do no particular harm except as it may interfere with a full crop of oats. Rye is the most vigorous of the small grains, and it may happen that next season's crop will contain more rye than oats. In that event we would advise cutting quite early so as to save the rye, which will ripen some time before the oats are ready to harvest. The rye will not injure the cows or their milk.

EASY CHURNING MILK.

Will you inform me why is it that milk that has been run through an aerator (Champion) will churn when on the delivery wagon.

Boston, Mass. D. L. R.

It is not probable that running the milk over an aerator will have any effect on the churning quality of the milk. The ease with which milk or cream will churn is dependent on several conditions, as the size of the fat globule, per cent of albumen, condition of the casein, etc. None of these would be changed by the process of aeration. The fact that butter forms in the cans only indicates that the fat churns very easy and it would do so regardless of the aeration.

BREEDING HEIFERS BACK TO SIRE.

Will you advise me as to serving my heifers to their sire? W. C. C.

Comet, Ont.

The primary question is not one of kinship, but of merit, individual and inherited. If the sire has special qualities that it is desirable to perpetuate and intensify, or, wanting these in any considerable degree, is the best bull you can conveniently have for service, there is no reason why he should not be used as suggested. A great majority of the best animals of all kinds are more or less inbred, —but are best not because of the inbreeding, *per se*, but because sire or dam, or both, were superior. But remember that inbreeding will just as certainly intensify defects as excellencies, and possibly somewhat more certainly. It is because of this fact, that inbreeding should not be carried too far.

SEEDING TO ALFALFA.

I would very much like to know if it is practicable to grow alfalfa in wheat as we do clover and timothy. If so, is it best to sow in the fall as we do timothy, or in the spring as we do clover? F. B.

Middletown, Del.

Alfalfa has not been much grown in this immediate vicinity, and we are therefore unable to answer very definitely, from personal experience or observation.

The "directions" usually given by those who have had experience, is to sow in the spring, and without any so-called "nurse-crop", which might be more appropriately termed in most instances, a robber-crop

The editors of this paper each tried seeding small fields to alfalfa last spring, one sowing the seed with oats, which were cut early for hay, and the other sowing the alfalfa alone. That sown with the oats came up nicely and seemed to do first-rate. For one thing, the season here has been very favorable, with plenty of rain, but had the oats been allowed to mature and thus put an extra burden upon the moisture in the soil, it is possible that less satisfactory results would have been obtained.

We have frequently noticed with new seeding of common clover, that the most trying time for the young plants is when the grain is ripening. It would not do to sow alfalfa in the fall.

Thoughts About The Silo.

ED. HOARD'S DAIRYMAN:—I am glad to see the dairy press pushing the silo to the front more earnestly than ever. It shows that our leaders are convinced that the silo is an indispensable factor in economical stock feeding, and that as many stock feeders as possible should know this for their own benefit.

With severe competition and consequent low prices, we can no longer afford to be wasteful and careless. Time was when farmers made money with their stock, if they wasted from one-third to one-half the feeding value of their corn crop, but that is no more. The editor says, "give us practical experience." Yes, that counts with the practical farmer every time.

Not long ago, at one of our farmers' institutes, a well educated and scientific lecturer gave a lecture on soil culture, in which he asserted that the usual method of plowing a hillside was all wrong. By throwing the furrow slice down hill it covers the hillside like a shingled roof, and sheds the water that should be caught and held for future crops. The furrow slice should always be thrown up hill, thus turn the shingles so as to capture the water and carry it where it is of benefit to the coming crop.

After he was through with his very nice and complete talk, an old farmer, without rising or addressing the chair, asked, "Did you ever try that?" The speaker admitted he had not, *his land was level.* The old farmer said: "Well, young man, whenever you are ready to put your theory into practice come to my place. I have the hills, the plows and the horses, that can walk pretty rapidly where the land is very stony, and if you show me how to make a decent job turning the furrow slice up hill, I will make you a very nice present. The young man would not volunteer to do the instructing.

Theories are very good to have around, but it is not always best to let them loose in a miscellaneous audience. So I think it well for the editor to qualify the writers on the silo to four or more years experience.

First trial experiences are sometimes clouded with too much enthusiasm, or possibly, prejudice. But after a man has fed his cows steadily for 300 to 365 days in a year, for four to six years, and has carefully kept an account with each cow and with the entire herd, and then compares the last five years with five former years when he had no silo. And then carefully lays over in his mind the *work* it *then* took to get the corn and stover before the cows, in a shape so most of it could be utilized, and the work he had to do day after day to cut and draw in the soiling crop, and how the drouth cut them down so he did not know where to get feed for his stock, and often had to sacrifice some for want of feed then, after the cows were compelled to roam over acres and acres of dry, brown, bare pasture in the boiling hot sunshine to search for a living,—only with such experience can he truly, emphatically and positively tell the other fellow the *real* value of the silo.

Now he stores his cattle feed in a few days for the whole year, in the finest, best, most digestible and most succulent condition imaginable. Instead of working hard to raise a big crop of corn, and then wasting a third or more, and feeding the rest in a very unpalatable state, he now saves it practically all, and it is all so palatable that it does his heart good to see the cows eat it.

He keeps twice as many cows as he did before, and much more than doubles his former profits, and really does not work as hard as he did under the old methods.

Under these conditions and with these experiences, he can earnestly and forcefully tell his fellow farmers that the silo is an absolute necessity, a great profit maker and labor saver. Indeed about every one that I interviewed has had just this experience.

The longer they use it the more they see the value of it, and the more they wonder how it can be that their fellow farmers are so bound and rooted in the old rut that they will not try to come out.

It is all very instructive and interesting to learn the facts and figures from our experiment station, that curing in the silo means a loss of 5 to 10%; while curing in the field means a loss of 25 to 35%, and that silage makes from 5 to 10% more milk per pound of dry matter than dried corn fodder, and that there is a corresponding increase in the yield of butter; the better condition of the cows in health and appearance, and a number of other deductions and results of experiments.

I say, all this is very good; but when the *actual, practical* farmer—the man who depends directly on the soil and its products for his entire living, and that of his family, the man who can and does hold the plow and milk the cow—takes his pen (and that man can always write plainly enough for the editor to decipher it) and tells his brother farmers that he had tried the silo for five years, and is now fully convinced that he can harvest the corn crop much easier and quicker than in the old way, and that as a feed it is worth nearly again as much as it is in the old way of curing, such testimony is effective.

By just such tactics, our patent medicine friends (I was going to say fiends) carry convictions to the unbeliever. Why should not we try to induce the farmer to come out of the rut and make use of a discovery that is one of the greatest blessings of the age? *Lessens labor, increases happiness, and lengthens life*; so much I can testify for the silo, after using it five years.

After a man has dropped some of his ultra-conservatism, and turned out of the rut so far as to conclude to build a silo, he can generally very easily decide just what he wants, and how he wants it.

He may have plenty of room in his barn, and he will cut off a corner, of, say 12×12 or 16×16 and 25 or more feet high, and if he has some timber to put in the extra studding, he can construct a silo there for 35 or 40 cents per ton capacity. Just such a box I have in my barn, and it is very satisfactory in every way, and were I to do it over again, I would have it right there. It is convenient to fill and feed.

Some farmers do not have the machinery, nor care to purchase, for cutting the silage, and therefore hire an engine and outfit, and fill the silo with a rush, while I have a cutter and tread power, and can nicely place 100 tons of silage into the silo in seven days, with my own horses and my regular help. I save money and have no general "hullabaloo" around the place, as is always the case when the threshing or cutting gang comes. I can also give my silage time to settle, and then fill up again, thus putting more corn into less space.

I have visited and investigated the workings of many different kinds of silos, and find them practically all satisfactory, if they are deep enough and the corn is put in at the proper stage of maturity.

To make a success with a silo is as easy as falling off a log, and ten times pleasanter.

Adams Co., Pa. L. W. LIGHTY.

Letter From Northern Vermont.

Remarks on the Season and Crops, With Some Lessons Gleaned from the Haying Field.

ED. HOARD'S DAIRYMAN:—The drouth which had been more or less severe over New England up to the first of July, was succeeded by plentiful rains. These were indeed most acceptable and of great benefit to the crops and the failing water supply.

Some of the meadows, particularly the older seeded ones, were past redemption, but much of the other portion was appreciatively benefited.

The yield of the crop, at least in Northern Vermont, has been considerably better than was anticipated a few weeks ago, while the quality, where not injured by the frequent rains—for this has been a "catching season"—will be good. This with the considerable amount of old hay on hand, must be sufficient for the purposes of the farm.

Corn and other grain crops promise an average yield, so there will be little necessity for Vermont farmers disposing of more than the usual amount of stock for lack of fodder.

The season is more favorable for pastures and meadows, so that with proper care the milk yield, which had been materially decreased, should be kept from further shrinkage.

Prices for milk and butter continue good and there now seems to be no reason why they should not continue so during the remainder of the season.

Considerable less butter is being received at the trade centers than a year ago; local consumption is on the increase, and with a fair export demand, prices to producers should remain satisfactory.

The wide-awake farmer should take advantage of this state of things to do his level best in producing just as much and just as good a quality of product as the means at his command will permit. This will pay, as every observing reader of HOARD'S DAIRYMAN has gathered from the successful experience of others, as given from week to week.

And now as to some of the lessons that should be learned during the season of haying.

First, and a very important one, is that of cutting the crop as nearly as possible when in its best condition. This requires some calculation and good management, a determination to commence early enough, so there will not be an appreciable loss at the end from the grass standing too long.

Too many wait until all of the grass is ready for the scythe before commencing, and then there is unavoidably more or less of loss in quality in the end. Many farmers observing this at the close of haying, resolve to commence earlier another year. This is well if the resolution is put into effect.

As a usual thing, the older seeded fields gave the lightest yield and often of the poorest quality, while a season like the present, reduces the yield still more sensibly. Here is where a shorter rotation, that is meadows a less number of years in grass, will give better returns. For instance, in raising more corn and oats for fodder, our fields are only in grass for three years and the present season, as a consequence I calculate, the field was as good as last year, when there was an unusual large crop. This is a result not to be overlooked.

Again if a farmer has manure for the purpose, it should be applied as a top-dressing for grass, at any time after haying, and on those places where it would be likely to produce the best results. This will usually be where there is a good set of grass, for it is quite largely run out. The method of recuperation will be of little use; the land should be plowed, devoted to other crops and seeded again to grass.

There are some pieces difficul to plow that can be kept in grass by frequent topdres ings of manure. A "little and often" will be found better than a single large application.

Many of the farms, at least in the Eastern states, are more or less stony. Where this is the case there is usually some work to be done every time the land is plowed in removing these obstructions, and with carefulness in removing these on seeding to grass, there will be some left, and where this is the case they are pretty sure to be found when getting the hay. After haying is a good time to remove these before they are forgotten. Clean, smooth fields are very desirable for cultivation and harvesting, and it will pay to bestow considerable labor and expense on them in fitting them properly for the production and gathering of the best amount and quality of crop possible. These I find are some of the lessons that can be learned while gathering the hay crop, and if they are only made the best use of, in the most practical mann r, the results cannot fail of being eminently satisfactory.

Franklin Co., Vt. E. R. TOWLE.

CHERRY'S Feed and Litter CARRIER

An invention for cleaning out barns and feeding stock. The most practical device of the present day. Send for circulars to D. B. CHERRY & CO., Knoxville, Marion Co., Iowa.

MARION HARLAND
has written four new books.
THE FARMERS VOICE
is the greatest Agricultural Weekly in the United States.
The Four Books and the Voice to Jan., 1900, for - 50c

The four volumes of Marion Harland are just out and are not on sale at the book stores. Vol. I on "Health Topics"—Vol. II, "Home Topics"—Vol. III, "Household Management"—Vol. IV, "Cooking Hints.' Finely printed on heavy paper from new type and plates. Bound in heavy paper cover. The retail price of each volume is 25 cents, $1 for the set. The Farmers Voice is $1 per year. The books will be sent you free of cost, postage paid, and the Voice to Jan. 1, 1900, all for 50c. This phenomenal offer will be open for a short time only. Address,
THE FARMERS VOICE, Chicago, Ills.

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,
67 Main Street, - Cortland, N. Y.

Mr. Wheaton's Canadian Dairy Notes.

Preventing Mold on Cheese.—The Use of Formalin. —Gravity Separators. — Dairy Markets.—Canadian Exports.

ED. HOARD'S DAIRYMAN:—Formalin has been used very successfully at the Black Creek factory this season for the prevention of mold on cheese. The curing room of this factory, which is owned by Messrs. T. Ballantyne & Sons, Sheatford, Ont., is built of brick and is considered one of the best in the province. Still the cheese when in the curing room for a short while became covered with mold, and to use the maker's words: "Got as black as your hat, during the months of June, July and August."

The cheese maker at the factory, Mr. Geo. Barr, who is one of our most enterprising dairymen, in writing of his experience with formalin, says:

"Last year we used formalin. At first I used a small atomizer to spray it on the cheese, but found it did very little good. I bought a tin sprayer, which was being sold for spraying potatoes, etc., and commenced using it to spray the formalin on the cheese, and found that the greater quantity of formalin I used the less mold there was on the cheese.

This season I commenced using the formalin as soon as we stopped using a fire in the curing room, spraying all the cheese every morning after the room was closed up for the day. We put as much on as a man can before he has to get out of the room, closing all the doors, and it is so strong in our curing room every morning for an hour or two that a person cannot stay in the room two minutes. The result of using it in this way is that our cheese are as clean almost as when they came out of the hoops. We used in June half a gallon of formalin, which cost $2.50. I consider it worth twice that amount to have cheese as clean and the curing room smelling as nice and sweet as ours does.

A great many cheese makers say formalin is no good. It seems to me they have not used enough of it. It will certainly destroy mold and I am satisfied that no curing room could be any worse for molding cheese than ours was. To have cheese as nice and clean as they are this year, makes me think a great deal of formalin, and I would advise any cheese maker to get a good sprayer—they can be bought at almost every hardware store, tin shop, or dairy supply house—and go to work and thoroughly saturate the curing room with formalin and then use it every day afterwards. We also use it in our curd sinks after washing them and find it sweetens them."

Mr. Barr's experience is certainly a very valuable one and if a liberal application of this substance to the cheese will destroy and prevent mold, every maker should use it. Mold on cheese is an unsightly thing to behold and if it can be cured so effectually by the above treatment and the cheese kept clean, a difficulty that many makers have to contend with, can be easily overcome.

Another important point in Mr. Barr's statement is the wholesome effect that the spraying of formalin has upon the air in the curing room and in keeping the curd sinks sweet and pure. This is just as valuable a property of formalin as that of preventing mold in the curing room. To have a substance at hand that will purify the sinks and the make room after the day's work is done, should be of very great value to every maker, who should get in a supply, if for no other purpose.

Hydro-lactic, gravity and dilution cream separators are receiving some attention on this side, in the way of a discussion in the agricultural press. In a recent issue of *Farming*, Mr. W. J. Kennedy, of the Iowa Agricultural College, and who, by the way, is a Canadian and a graduate of the Ontario Agricultural College, contributes a rather exhaustive article on this subject, dealing chiefly with experiments that have been carried on to test the claims of these separators. He points out that during the past few months they have tested a number of samples of skim milk from these "separators" sent to the College, and the results showed that the per cent of fat in the skim milk varied from .8 to 1.4 of one per cent. One of those "separators" was on trial at the Iowa College and after being operated according to the instructions of the manufacturers for some time, the average per cent of fat in the skim milk was found to be .85 of one per cent.

This experience in itself would be enough o condemn such a system as not being economical and causing a large loss of butter fat in the skim milk, but Mr. Kennedy advances further proof and cites an experiment conducted at the Ontario Agricultural College, as follows:

"At the Ontario Agricultural College, the Hydro-Lactic Cream Separator was given thirteen trials, and the diluted milk was allowed to stand from six to twelve hours before skimming. The average per cent of butter fat found in the skim milk was .6 of one per cent, while the average of five years' work done with the centrifugal separator, the deep setting and the shallow pans was as follows:

No. of tests.	*Pounds of milk skimmed.*	*Method of skimming.*	*Average per cent Butter fat in skim milk.*
150	7,600	Separator.	.10
150	7,600	Deep setting	.31
150	7,600	Shallow pan	.38

At the Vermont Station, Prof. Hills used the "Wheeler Gravity Separator," and obtained the following results:

Character of milk.	*Average per cent of fat.*	*Dilution.*	*Number of trials.*	*Per cent of fat in undiluted skim milk.*
Herd milk, mostly Jersey grades	5.00	2-5 milk, 3-5 water	39	0.63
Herd milk, mostly Jersey grades	5.00	" "	3	1.05
Stripper (Jersey) milk.....	5.50	" "	28	0.78
Stripper (Jersey) milk.....	5.50	" "	27	1.13
Ayrshire milk.....	3.75	½ milk, ½ water	23	1.50

These tables show pretty conclusively that these so-called separators do not compare at all favorably with the centrifugal method; and while they may be supplied to dairymen at much less cost than the regular cream separator, in the end they really cost more, as the loss of butter fat in the skim milk will soon more than make up for the extra amount paid for a good centrifugal machine.

Then there is the dilution of the skim milk to be considered, which renders it less valuable for feeding purposes, not to say anything of the injurious effect that might result from the addition of impure water. Taking all these things into consideration there is nothing to be gained, and much to be lost to the private dairyman in investing in one of these "pseudo" separators.

In dairy market circles things are looking bright. Both the cheese and butter markets have ruled firm during the week (July 22d), and everything seems to point to good prices for the balance of the season.

The bulk of the June cheese is out of the factorymen's hands, and what is better still, has gone forward to the British market, there not being so much held on this side as last year at this time. Shipments so far this season from Montreal show an increase of 80,000 boxes over the same period a year ago. But while this is the case, it must be remembered that at the beginning of the season there was a shortage of 250,000 boxes in last season's output. With a good consumptive demand in Great Britain and no accumulation of stock, the outlook for cheese is bright and Julys are likely to bring a good figure.

Finest Western is quoted at Montreal at 8⅞ to 9c, and finest Eastern at 8⅝ to 8¾c. At the local markets, during the week, prices have ranged from 8½ to 8⅞c, with 8⅜ to 8¾c per lb. the ruling bids. To-day (July 25) July cheese sold at 9 1-16 to 9 3-16c, on the local markets.

The exports of Canadian creamery butter so far this season show an increase of fully 82 per cent over those for the same period a year ago, and there does not appear to be any lessening of the demand for Canadian goods in Great Britain. Our creamery butter seems to be gradually growing in favor over there, and some sales made this season on the open market in England have brought as high prices as were paid for the best Danish on the same day. While our exports have increased 40,000 packages this season, those from New York have decreased nearly 22,000 packages.

Holders of fancy brands of creamery are asking 18½ to 18¾c for it, and sales are reported at Montreal at 18⅝ to 18¾c, per pound, which is nearly a cent above the best prices a week ago. At these prices the dairyman should have nothing to complain of in regard to his summer output. It is only a few years ago since he was compelled to accept about 16c for the same quality of goods.

Toronto, Canada. J. W. WHEATON.

Hydraulic Separator Science.

"Milk consists of butter fat, kasine(?) and water. *The butter fat, when it comes from the cow, is in the form of an oily substance; this will form into butter globules when cold*, and a portion will in time raise to the surface, while a large amount will remain in the milk unless removed by artificial means. By our operation, we take the warm milk and by means of our automatic separator we force numerous small streams of cold water into the milk which chills and hardens the butter globules (cream), and in their upward course force them to the surface."—*Extract from a Hydraulic Separator Circular.*

The above is exceedingly valuable information. It must be so or it would not persuade a dairyman into paying $10.00 to $15 for a $2.00 tin can and the privilege of adding water to his milk.

Both the tin can and the process are exceedingly valuable—from the agents standpoint. There is no doubt that he is correct. He makes a profit of several hundred per cent on the can, and the process is all profit. And the dairyman's profit(?)—well he doesn't get any, except experience, which we all know is valuable.

In the trials of dairymen accused of poluting milk, by the addition of formaldehyde, as a preservative, in Indianapolis police court last last week, evidence of a scientific character was introduced, that the substance retards digestion. Dr. Frank Morrison, president of the city board of health, presented the results of a most thorough and extensive series of experiments, in which "milk containing the greatest quantity of formaldehyde was not digested at all, while that containing the smallest quantity was just beginning to be converted. Pure milk which underwent the same process for twenty-four hours, showed that it had been quickly digested." It is said that Dr. Morrison proved that formaldehyde in milk was not only injurious to health of adults, but was the cause of inanition in children.—*Jersey Bulletin.*

Does Your Head Ache?

Are your nerves weak? Can't you sleep well? Pain in your back? Lack energy? Appetite poor? Digestion bad? Boils or pimples? These are sure signs of poisoning.

From what poisons?

From poisons that are always found in constipated bowels.

If the contents of the bowels are not removed from the body each day, as nature intended, these poisonous substances are sure to be absorbed into the blood, always causing suffering and frequently causing severe disease.

There is a common sense cure.

AYER'S PILLS

They daily insure an easy and natural movement of the bowels.

You will find that the use of

Ayer's Sarsaparilla

with the pills will hasten recovery. It cleanses the blood from all impurities and is a great tonic to the nerves.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentation to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, **$25.00**

Silo Experience and Advice.

ED. HOARD'S DAIRYMAN:—In the DAIRYMAN of the 21st, "Silo Experience" and "Advice Wanted" is called for. I have had eighteen years' experience with a silo 12×24 in one corner of a barn 40×50, extending into the earth nine feet below the feeding floor and twenty-one feet above it. The balance of this story of the barn stables thirty-four cows. The manure and waste are dropped through the floor into the story below, which is emptied about three times in the season, particularly in the winter. It never freezes to a serious extent, being occupied mostly by hogs, sufficiently warm and cool so they don't pile up and smother. If objection is made to this arrangement or further information is wanted, I am ready to explain.

The upper story is twelve feet high and accessible by a grade driveway. It is used for storage of forage, a two-horse Smalley tread power, fodder cutter, etc.

I mention these facts as a sort of preface or certificate of introduction to the readers of the DAIRYMAN, not as a copy for others to follow, but to show that I have had experience, and ought to know what I am talking about.

My remarks will be mainly directed to Mr. Kerr, of Jamaica, who, I suppose, resides in the West Indies, and J. B., of Greenville, N. C., although two Southern Professors who have interested themselves in this direction, may do well to look it over.

Mr. K. says he cannot extend his cistern lower for silo purposes without great expense. He does not state whether the cistern is rectangular or oval. An oval shaped wall can usually be held in place with a plastering of good cement on the earth, if not subjected to freezing. Some cellars in this latitude of 43° are cemented on straight lines, but I would not recommend them. I have known several square cisterns (straight lines) made to hold water, but I never knew one to hold water in or to hold water out. The best cistern I ever saw was sunk about two feet, ten feet in diameter, and walled up with stone and cement and then excavated about twelve feet more and well cemented on the earth wall, which was a sort of hard clay gravel. It was protected with a house over it that prevented freezing.

From my observation in this line I claim that a circular structure can be made in the earth as much as twenty-four feet in diameter and say twelve feet deep, if well cemented, and the top is protected from abrasion with stone, brick or even lumber. If said rim of protection was one or more feet wide I would risk extending it upwards twelve or even more feet higher with a tank silo, but I should prefer to make the upward extension studded with 2×4, and clapboarded on the outside with something that would bend to the circle—basswood siding would bend to a sixteen foot circle. If the silo was twenty or more feet in diameter good ship lap lumber would bend to the circle and would be better and stronger. I would set the studded frame back of the edge of the circle at least eight inches. Now here comes the objection of a shoulder which we should not have in a silo. To overcome this I would cut 2×4 into pieces about two feet long and spike them to the lower end of the studs with a slant to the edge of the wall below. This two feet I would lath with tobacco lath and plaster well with cement. Above, I would cover the studs with half-inch lumber, then with building paper, then over that another covering of half inch lumber and I believe we would have a good, complete silo if the cemented walls were kept from freezing.

But the objection will be raised "that cement wall will cave." Then make it of solid masonry, which in many places can be done cheaply. Mind you, this advice is for Mr. Kerr, J. B and Prof. Hart of S. C., also others in Southern latitudes. I resided in Columbia, S. C., from 1839 to 1847, and have a knowlege of their red clay, and I say with great confidence that I would not hesitate to build a silo on the plan proposed. But I should not stop there; I should like to have this silo at the edge of a bank if possible eight feet high. Around the silo I would make a lean-to say fourteen feet wide for a basement stable, the building being say forty feet in diameter more or less, according to size of silo. This would give room for thirty or more cattle, stalls heading to the center—plenty of room to get to their heads to feed the heavy ensilage, or more bulky feeds—plenty of room to drive a horse and cart around and out, to clean the stable, perfect protection from inclement weather and flies and other pestiferous insects in the heat of summer.

If the silo was in the earth ten feet, more or less, then eight feet more above to top of basement, where there could be a floor approached from a grade driveway—the ensilage cutter could stand on a strong table, five feet high, which would make a silo twenty-three feet deep, that could be filled without an elevator or carrier, and easily weighted, which if done, such a silo would hold as much ensilage as the ordinary, unweighted silo, thirty feet high.

If the basement lean-to should be carried up twelve feet more, and finished for a barn, it would give ample storage room for hay, straw, etc., for the season's use.

If I resided in South Carolina, and had stock to provide for, I would have a silo in the earth, a round hole in the red clay without cement or protection even, if I could not do better. But I could do better. I could protect the top with a lumber circle, say a foot wide, and above this, I could add on that a circle of stove pipe iron, which would make it two and one-half feet higher, then another width making four more or fifteen feet, all filled without a carrier; filled and refilled as it settles, and then covered with a good coat of earth. Top it, when you get ready.

To all, both north and south, I would say, have a silo, put it in the earth ten feet, and then on up; that ten feet below, and the first eight feet above will be the best and handiest part of the silo, however high you may go. And you will find that a wall cemented on the earth in a circular form will prove stronger and more durable than you supposed.

The silo requires strong, air tight, smooth walls; the silage weighted if conveniently possible. F. C. CURTIS.

Columbia Co., Wis.

Thirty Years Silo Experience.

ED. HOARD'S DAIRYMAN:—As my experience extends back for thirty years, I will tell it for the benefit of those that contemplate building a silo, and, if possible, prevent them from making the expensive blunders in building that has been my lot to experience.

I built the first silo made in Sullivan County, N. Y., over thirty years since. At that time the agriculture papers advocated that they must be made mostly under ground, to prevent them from freezing, and as I did not know of any near me that had any experience, I made the first one to be frost proof at a large expense.

I built it at one end of my basement barn, excavating out of red slate rock 18×30×14 feet deep, using large quantities of cement to smooth up the rock on the sides and on the bottom.

We filled it with good state corn with tolerable success the first season, and was very much pleased with my new departure, that the neighbors were watching with all sorts of prophecies in regard to the sour, unpalatable material, as they all called it, that was taken from the pit.

But was myself very much pleased with the proceeds had from milk that was made from that pit of corn and was satisfied that I had made a good strike.

The second season I was not so fortunate. The fall and winter months being very wet, the water got in the pit, and spoiled three or four feet in the bottom. The third and fourth seasons the same and I abandoned the use of silage for three or four years, but was not satisfied in doing without what I had had experience enough with to know was the cheapest and most profitable manner of disposing of a crop of corn.

At the same time being convinced that silage was the cheapest and most desirable product that was at hand for the production of milk, I resolved to build another silo on the following plan and dimensions:

We dug in the earth five feet, stoned it up, put sills on foundation, so that they projected four inches, used 2×10 studs on sills, twenty-one feet long and 2×4 under the sills to the ground. Double boarded, with rough lumber, with paper between, making a silo 17×18, twenty-six feet high.

It answered a good purpose, only the corners were badly decayed. We have remedied the corners of wasting by using a breadth of tarred paper every season in each corner, putting it on the old every season.

The variety of corn makes a vast difference in the keeping qualities. Our state corn is very liable to get too ripe to keep perfect without watering it finely. In late years I counteract the ripeness by mixing western corn, about one to five, which makes sufficient moisture to save in good condition.

Late years there have been several parties to look me over and get advice in regard to the building of a silo and other things in regard to silage, and have advised the building of stave silos and to build them above ground, without there was perfect drainage.

I am sure it is the most economical manner of building, that the silage settles more perfect and can exclude the air so as to prevent decay.

"Life is too short to learn it all by our own experience," and if the above, that you called for, will be of any service to you or your patrons, you are welcome to it. If not, the waste basket is generally in the editor's office, handy by. B. W. G.

Liberty, N. Y.

Butter Tests from the St. Omer Herd.

ED. HOARD'S DAIRYMAN:—We take great pleasure in forwarding to you two St. Omer butter tests, which simply shows what they (our Jerseys) are doing every day. Hazel Fan 3rd, 143352, without any preparation whatever beforehand, gave for the seven days, ending February 1st, 1899, 216 pounds of milk, showing by the Babcock 5.6% butter fat, and churning according to the A. J. C. C. rules, 14 pounds and 4 ounces of prime butter. She calved December 28, 1898, and at time of test was about 5 years and 5 months old, and weighs about 850 pounds.

She was fed daily a mixture of thirty pounds of good corn ensilage, five pounds crimson clover hay (cut) seven pounds of wheat middlings and two pounds gluten meal, besides one peck of roots daily.

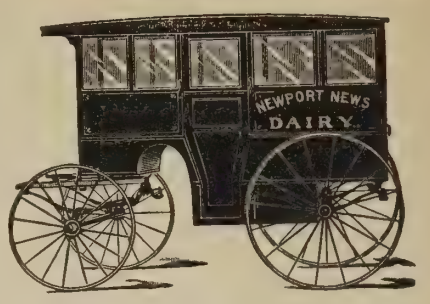
She was sired by George M. 46197, he, by Geranium's Rajah 18605 and out of Signal Queen 30689 (one of the high standing Columbian cows) while her dam was Hazel Fan 16814, a good cow of old lines of breeding

Aunt Mary 4th 95134, calved April 26, 1899, and finished her week's test July 23, 1899, at six years and four months old. She was running on burnt up pasture, and received a small quantity of green corn silage, with twenty pounds of mixed (equal bulk) of bran and hominy chops.

She gave 270 pounds of milk, testing by Babcock, 4.8% butter fat, from which we made 16 pounds, 4 ounces of unsalted butter, salted one ounce to the pound and the butter ready for the market weighed 15 pounds 4 ounces.

She was bred by Mr. Dinsmore, of New York, and sired by Exile of St. Lambert 23rd, and out of Aunt Mary 30495, a descendent of old Emperor. J. T. HOOPES.

Bynum, Md.



Spongy Curd and the Effect of Sewage.

The following paragraphs from Professor Lloyd's Observations on Cheddar Cheese Making, contain some valuable information for cheese makers, who are, during the present month especially, often troubled with tainted milk and gassy curds:

Spongy curd was present only to a slight extent (during last season), and when present the cheeses always contained one or other of those organisms which have been described in former reports as giving rise to spongy curd. As then pointed out, the chief source of these organisms is cow dung, which has been allowed to get into the milk either by accident or carelessness. A striking illustration of how this trouble may arise happened at Long Ashton in 1898. One day the curd was terribly spongy. Inquiries were at once made to ascertain what had happened out of the ordinary course. It was found that some of the cows had been allowed to get into a paddock, adjoining the yard, where there was a pool of stagnant dirty water, from which some of them drank and into which, of course, they went, more or less. The cows managed to get into this paddock twice, and each time a spongy curd was produced. To make sure that the water was to blame, I had it examined bacteriologically, and found in it one of the most typical spongy organisms, and this was also found in the curd when it was spongy.

If even the least trace of cows' dung gets into the milk, it will give trouble in cheese making. Far worse, however, is the effect of sewage. It not only produces taints similar to those produced by cows' dung, but others also. When, therefore, some time later such taints arose in the curd, and it was found that the cows had not been into the paddock adjoining the yard, a new source had to be looked for, and was at last discovered. The field Hop and Mead is on a slope of a hill, on the top of which are some cottages. The sewage from some of these cottages is allowed to pass into a receptacle in the rock, which, when it is full, overflows on to the Hop and Mead. This appears to have happened early in July, and when the cows were next turned out into this field, the curd became both spongy and tainted with a peculiar taint that had not been previously noticed.—*The Dairy*, (*England.*)

The World Cannot Show Its Equal

In STYLE, CONVENIENCE and DURABILITY.

Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairyman at bed rock prices. For description and price address,

THE NATIONAL WAGON CO.,
Chillicothe, Ohio.

A Low Wagon at a Low Price.

In order to introduce their Low Metal Wheels with Wide Tires, the Empire Manufacturing Company. Quincy, Ill., have placed upon the market a Farmer's Handy Wagon, that is only 25 inches high, fitted with 24 and 30 inch wheels with 4 inch tire.

This wagon is made of best material throughout, and really costs but a trifle more than a set of new wheels and fully guaranteed for one year. Catalogue giving a full description will be mailed upon application by the Empire Manufacturing Company.. Quincy, Ill., who also will furnish metal wheels at low prices made any size and width of tire to fit any axle.

Wisconsin State Fair,

MILWAUKEE, Sept. 11, 12, 13, 14 and 15, 1899.

Cows and Cows.

When we were buying cows occassionally it was not much satisfaction to us to have the one who wanted to sell one tell us she gave so many quarts a day "in the best of the season." We had handled cows and milk for years, and in selling milk would have been willing to have obtained considerable less in the flush time if we could have got more in the worst of the season.

We had owned two cows standing side by side in the barn and running in the same pasture, one of which gave eighteen to twenty quarts at her best, while the other never excelled fourteen quarts a day. The eighteen-quart cow received the most grain, but shrank to twelve quarts as soon as the other, and to six quarts before the other did to eight, while she went dry nearly a month earlier, and did not keep in as good flesh. We think if the milk had been weighed every day, the fourteen quart cow would have had the best record for the year.

A test made three or four months after calving, and another two months later, gives a much better idea of the quality of the cow, than one made when she is fresh; but the weighing of the milk for the year tells the whole story; 6,000 pounds of milk, or nearly 3,000 quarts, is a good record. It is an average of about nine quarts a day for eleven months, and a cow which gives twenty quarts or more, when fresh, ought to reach very near that.

Many times, when they do not, it is not the fault of the cow. The drying up of pastures, and no green food ready to give her; an unwillingness to feed any grain in summer in the idea that it is not needed, and but little in winter, because she does not give enough to pay for it; no shade in summer to protect from the heat, and a too well ventilated barn, which does not protect from the cold in winter; irregular hours of feeding and milking, and a lack of proper care generally, may reduce a 6,000-pound-a-year cow to two-thirds of that amount.

The man who exchanged cows with the old quaker to get one which would give more milk, decided at last that he should have swapped pastures instead of cows, and perhaps there were some other points in their treatment which he could have changed to his advantage and that of the cow.—*American Cultivator.*

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade was unusually small, but 4,800 pounds being placed. No bids were made, and consequently there were no sales. The Quotation Committee announced the market steady at 17½ cents.

The sales for the corresponding week of the three preceding years were as follows:

Aug. 1, '98, 7,260 lbs. of butter sold at 18½c.
Aug. 2, '97, 15,000 lbs. of butter sold at 14½c.
Aug. 3, '96, 24,480 lbs. of butter sold at 14¼@14½c.

The New York market, Monday, was reported steady at 18 cents. H. C. B.

Elgin, Ill., July 31, 1899.

DAIRY MARKETS.

ELGIN, Ill., July 31—Eighty tubs offered; no sales. Committee reported steady, 17½c.

CHICAGO, Ill., July 31—Butter—Creamery, extra, 17@17¼c; firsts, creameries, 16@16½c; seconds, 14@15c; dairies, selections, 15@15½c; No. 1, 14c; No. 2, 12½c; extra ladles, 13@13½c.

Cheese—Full cream Twins, new, good to choice 8¾@9c; Young America. 8¾@9c; Swiss, 9@10¾c; Limburger, 7@8½c; Bricks, 7@8¾c.

Eggs—Fresh, at mark, cases returned, sold at 10@10½c; loss off, cases returned, 12c.

Bran—Scarce and in demand at $11.75@12 per ton.

Cattle—Receipts were comparatively small and the demand active. Prices ruled steady to 10c higher. The good to choice beef cattle showed most of the advance. Exporters bought 1,500 steers, averaging 1,230@1,410 pounds, at 5.40@5.75. Three loads of 1,377-pound steers sold at 5.85, with very few beef steers below 4.75. Some fed western steers reached 5.75; Missouri and Iowa fed Texas steers, 960@1,166 pounds, 4.65@5.40; distillery fed steers, 1,358 pound steers, 5.45; straight Texas steers, 1,148@1,201 pounds, 4.95@5.20. Most of the feeding cattle sold at 4.10@4.60. Distillery fed bulls, averaging 1,206 pounds, sold at 4.50. Several carloads of good cows sold at 3.85@4.45. Heifers sold principally at 3.90@4.60.

MILWAUKEE, Wis., July 31—Butter—Creamery, fancy prints, per pound, 17½c; extras, 17@17½c; firsts, 15@16½c; seconds, 14@15c; imitations, 14@15c. Dairy, selections, per pound, 14c. Market unchanged; trade and supply fair; receipts, 15,110 pounds.

Cheese—American full cream, new, choice to fancy, 9@9½c; Brick, new, per pound, choice, 8@8¾c; Limburger, new, choice, per pound, 8@8½c; Swiss, drum, choice, 12½@13c; new block, choice, 10@10½c. Market steady; receipts, 10,297 pounds. Trade fair.

Eggs—Fresh, per dozen, 11@11½c, loss off cases returned. Markets unchanged, with receipts of 311 cases. Trade quiet.

PLYMOUTH, Wis., July 24—The sales reported on the Plymouth dairy board to-day were 1,375 Twins at 9c and 900 cases Young Americas at 9c.

HILBERT, Wis., July 22—At the meeting of the new call board the following sales were made: 100 cases Young Americas at 8⅝c; 25 at 8¾c and 20 Twins at 8¾c.

BRILLION, Wis., July 21—The sales reported on the Brillion dairy board were 445 cases Young Americas at 8⅝c, 100 at 8¾c, 784 Twins at 8⅝c, 65 at 8¾c, 1,394 Daisies at 8⅝c.

APPLETON, Wis., July 31—The offerings at the Outagamie County Board of Trade were: Cheddars, 365; Twins, 1,153. The sales were: 445 Twins at 9c, 427 Twins at 8⅞c, 159 Twins at 8¾c, 286 Cheddars at 8¾c. The offerings at the Appleton Dairy Board were 129 Cheddars and 401 Twins. The sales were 238 Cheddars and 50 Twins at 9c.

AVOCA, Wis., July 31—On the Lone Rock and Muscoda Dairy Boards today the offerings were 1,007 boxes Twins at 9c; Daisies at 9¼c; market firm and all sold.

FOND DU LAC, Wis., July 31—Offerings, 687 Twins and 532 Daisies; market firm; Twins, 9⅛c; Daisies, 9½c.

SHEBOYGAN FALLS, Wis., July 26—There were 1,045 boxes of cheese offered on the Call Board to-day, and was all sold as follows: 580 cases Young Americas, at 9¼c; 115 at 9⅛c; 115 at 9¼c; 182 Twins, at 8¾c, and 168 Daisies at 9⅜c.

MANITOWOC, Wis., July 26—Offerings of cheese at Dairy Board of Trade to-day were 800 boxes Daisies, 135 boxes Twins, 900 boxes Young Americas. All Daisies and Young Americas sold at 8¾c; 35 Twins, at 8⅝c and 100 at 8¾c.

HORTONVILLE, Wis., July 27—Offerings on the board to-day were 396 boxes Cheddars and 1,053 boxes Twins. All sold at 9c and 8⅞c.

PHILADELPHIA, Pa., July 31—Butter—Solid packed separator creamery, extra, 18½c; creamery, firsts, 18c; seconds, 16@17c; imitation creamery, extra, 16c; firsts, 15c; seconds 13c; ladle packed, extra, 14@14½c; firsts, 13½c; seconds, 13c; print butter, creamery, extra, 21c; firsts, 20c; seconds, 18@19c.

Eggs—Pennsylvania and nearby, 13½c; Western, 13¾@14c; Southwestern, 13c; Southern, 10@11c.

ST. LOUIS, Mo., July 31—Butter—Steady; creamery, 15@18c; dairy, 12@15c.

Eggs—Slow; 9c.

KANSAS CITY, Mo., July 31—Butter—Creamery, 14½@16½c; dairy, 14c.

Eggs—Fresh, 8½c.

CINCINNATI, O., July 31—Butter—Quiet, 18½@19c.

Eggs—Dull; 9c.

Cheese—Firmer; good to prime Ohio flat, 8¾c.

NEWARK, N. J., July 31—Market quiet; 18c for fancy creameries. Receipts liberal.

WASHINGTON, D. C., July 31—Market steady; extras, 18½c; firsts, 17c.

NEW ORLEANS, La., July 31—Market steadier, 18½@19c.

BOONEVILLE, N. Y., July 23—There were no sales on the regular board. The curb sales were: Large colored, 645 boxes, 8⅜@8½c; large white, 260 boxes, 8¾@8½c; large white, 120 boxes, 8½c. The salesman of the Spring Brook factory of Booneville received 8¼c.

LITTLE FALLS, N. Y., July 24—This market shows a good improvement since last week, prices being ¼c advance on small cheese, but large remain about the same. The sales were 6,252 boxes at 8¼c for all styles.

WATERTOWN, N. Y., July 24—The official sales aggregated 600 boxes, which went at 8⅜@8½c. On the curb the sales were: Large white, 6,045 boxes at 8¼@8⅞c; Twins, 400 at 8¾@9c. On the curb there were about 2,360 boxes sold at 8¾c and 3,400 boxes sold at 8⅝c, the latter price ruling.

UTICA, N. Y., July 24—Responding to a higher cable, advanced figures at the primary markets during the past week, a firm tone at distributing centres, business on the Utica board to-day was active, and the ruling price for large sizes was ½c higher than last week, while that for small was ¾c higher. The range for the entire market was from 8¼@8⅞c, as against 8@8¾c last week. Following is the list of sales: 119 lots, 9,624 boxes at 8¼@8⅞c.

The transactions on July 26, 1897, were 10,575 boxes with the ruling price 7c. The transactions on July 25, 1898, were 8,746 boxes with the ruling price 7c.

Although the tone of the butter market is not as strong as it has been of late there were 152 packages of creamery sold to-day at 18c.

CANTON, N. Y., July 24—On the market Saturday 2,000 boxes of cheese were sold at 8¾c.

There were 1,300 tubs of butter sold at 17⅝c.

OGDENSBURG, N. Y., July, 24—1,651 boxes of cheese were offered. A bid of 8¾c resulted in no sales, but on the street afterward all were sold at 8⅞c.

FULTON, N. Y., July 24—On the board to-day 19 factories were represented with 1,625 boxes of cheese. Large sold at 8½c and small at 8¾c.

NEW YORK, July 31—Butter—Creamery, western extras, 18c; western firsts, 17@17½c; state extras, 17½@18c; state firsts, 17½@18c.

Cheese—State, full cream, large or small, colored or white, choice, 9c.

Eggs—State, Pennsylvania and western, 15@16c.

LIVERPOOL, July 31—Butter—Finest United States, 86s; good, 63s.

Cheese—American finest white, 44s; American finest colored, 44s 6d.

NEW YORK MARKET.

NEW YORK, July 29.—Butter—Receipts for the week were 49,140 packages; exports for the week were 10,007 packages. Exporters started early and were free buyers up to the close of the week's business; the bulk of their purchases were good to fine creameries at prices ranging from 16 to 17½c; this, together with liberal sales to Eastern and Southern buyers at about the same prices, have caused a better feeling, and the market is closing with less offerings of these grades butter. Local trade bought more liberally of extra creameries at 18c and finest N. Y. State dairy makes at 17 to 17½c. Ladle butter is quiet, but holders of fine June goods are firm. We quote:—Creamery, extra 18c; medium 17@17½c; poor 15@16c; dairy, extra 17@17½c; medium 15@16c; poor 12@14c; ladle, extra 14@15c; medium 13@13½c; poor 12@12½c.

Cheese—Receipts for the week were 44,741 boxes; exports for the week were 22,580 boxes. The market is strong and buoyant. Arrivals are well cleaned, and with full prices in the interior of the State our market closes firm with quotations easily obtainable. Sales for export are reported at 9c for large sizes, while small cheese have sold readily at 9@9¼c. We quote—Full Cream small, extra 9@9¼c; medium 8½@8¾; poor 7@7½c. Full Cream, large, extra 9c; medium 8@8½c; poor 7@7½.

Eggs—Receipts for the week were 49,176 cases. Strictly fresh eggs sell on arrival at top quotations; all other grades are abundant, hard to sell and prices nominal. We quote—New York and Pennsylvania, per doz. 15@15½c; Western and Northern, best marks 14½@15c; other sections, 12@14c. DAVID W. LEWIS & Co.

177 Chambers St., N. Y.

BALTIMORE, Md., July 31—Butter—Market steady; creamery separator, extra, 20c; extra first, 18@19c; creamery first, 17@18c; creamery imitation extra, 15@16c; ladle extra, 14@15c; Western Store-packed, 11½@12½c.

Eggs—Market easy; strictly fresh stock, 11@11½c.

BALTIMORE MARKET.

BALTIMORE, Md., July 27—Butter—If the committee which rules over the prices of butter and has its seat of government on the Board at Elgin, would realize their power, being great men, we believe they would hesitate to use it just for the purpose, apparently, of keeping the butter world guessing, and increasing the mental misery of all of the dealers in creamery outputs, now in the time of their physical discomfort, when reeking of a humidity that collars cannot stand, and under which the sweetest tempers sour. Last week all offerings were sold at 17 cents, yet the market was declared by the committee "steady at 18 cents," well, that would only provoke a smile on the lips of the esoteric; but this week the order was the reverse; 18 cents was bid for all, but the market was declared to be 17½, and straightway every cutter of every degree of importance, from the puny peddler of picayune proportion, to the pompous purveyor of lots and lines, wanted a half cent reduction in price of goods in stock, because, as they put it, Elgin had declined that much, and they invariably want a decline to work ex-post-facto, but are not willing that an advance should. And so the smooth surface of a nice summer business is agitated and ruffled by the antics of the disturbing west, and the brisk currents of a returning trade are turned away and into competing markets. Gathered cream makes were more or less affected in prices by the marking down at Elgin, and as the weather continued to get in its work on the quality, to some extent the salesman's lot is not a happy one. Ladles and imitation creamery are growing scarcer and scarcer, but the quality grows poorer, of current make, and that makes it difficult to maintain prices for all receipts. Store-packed continues in light receipt with good demand, although the grading of much of it is very low.

Creamery separator, extras, per pound, 19c; firsts, 18c; seconds, 17c; gathered cream, extras, 17@18c; firsts, 17c; seconds, 16c; Ohio, extras, 17@18c; firsts, 17c; seconds, 16c; imitation, extras, 16c; firsts, 15c; seconds, 14c; Iowa & N. W. ladle, extras, 14c; firsts, 13c; seconds, 12c; Ohio & Indiana ladle, extras, 14c; firsts, 13c; seconds, 12c; Ohio store-packed, 12½@13c; firsts, 12c; W. Va., extras, 12½@13c; firsts, 12c; creamery blocks, (2 lbs.) extras, 21c; firsts, 20c; seconds, 19c; prints, (½ lb.) extras, 21c; firsts, 20c: seconds, 19c; Md. Va. & Penn. prints, extras, 19c; firsts, 18c; seconds, 16@17c.

Eggs—There is a fair demand for all choice fresh eggs at 11 to 11½ cents; the receipts of this kind are ample for the demand; the stock must be A No. 1 to meet the requirements of the trade. Heated and other tender stock are not only dull sale, but prices irregular, and when a sale is made it is generally in the buyer's favor.

Cheese—The receipts of cheese are light, the demand fair; market firm.

N. Y. State Cheddars, fine, 9¼c; choice, 8¾@9c; fair, 8¼@8½; Flats, fine, 9½@9¾; choice, 9@9¼c; fair, 8½@8¾; Small, fine, 9¾@10c; choice 9¼@9½c; fair, 8¾@9; Ohio Flats, fine, 9@9¼c; choice, 8½@8¾c; fair, 8@8½c; Picnic, fine 9@9½c: choice, 8½@8¾c; fair, 8¼c; Swiss, 13½@14, choice, 12@13; fair, 11c.

G. M. LAMB, & BRO.

301 Exchange Place.

Latest quotations for fancy creamery, Buffalo, 18½c; St. Paul, 16½@17c: Minneapolis, 16½@17c; Detroit, 19c.

FOREIGN MARKET.

BOSTON, July 29,—Cable advices of this date from the principal markets of Great Britain to Geo. A. Cochrane give butter markets as somewhat better with prices a shade higher. Danish selling at 22@22½c, finest Irish creamery 20@21c, and in Canadian, in boxes, at 20c@20½ The exceptionally fine quality of Canadian now landing and its splendid condition makes it the most favorite butter on the market. Ladles are doing slightly better, the light arrivals have enabled receivers to make 15@15½c. Imitations have sold in a small way at 16½@17c. Some American creameries just landing, but not enough business has been done to establish values this week.

Cheese markets show additional strength in consequence of the large consumptive demand, which prevents any accumulations in stock. Finest American and Canadian selling freely at 9½@10c.

Cleaning Separators.

Those who buy other makes of separators in the mistaken belief that they are getting something cheaper than an "Alpha-De-Laval" machine, are frequently helped to do so through understanding that an Alpha disc bowl is intricate and difficult to clean.

There could be no greater mistake. The "Alpha" is the most easily, simply and completely cleanable of all separators. The bowl is easily and quickly taken apart, and the discs are easily and simply handled, and completely cleanable. Every point of the whole bowl is easily accessible, both to eye and reach. All other bowls possess inner cylinders, cones, wings, flanges, tubes, cavities, and various stationery fixtures of one kind or another which are not removable, or only partly so, and cannot be reached nor seen, nor thoroughly cleaned, regardless of the time that may be devoted to it.

Not only may an Alpha disc bowl be thoroughly cleaned, more quickly than any other make, but when an Alpha bowl has been cleaned the user *knows* it is clean, which is not true of any other bowl.

If those who listen to the representations of competitive agents, who can't say a word against the superior efficiency of the Alpha machines, but necessarily have to talk about *something*, would only take the trouble to try an Alpha machine themselves, or to go through the illustrations shown in a De Laval catalogue, they would frequently save themselves from making a bad investment in a poor separator through misunderstanding of the actual facts.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Wanted—About Dec. 1st, two first-class single men to work on dairy farm. Must be of good habits. Permanent employment to right parties. A. L. FITCH, Westmoreland, N. Y. 24-1

For Sale—Bull calf, Combination blood, $20.00. Send for pedigree. JOHNSON STOCK FARM, Osceola, Ark.

Wanted—Two-horse tread power, second hand, and second hand shredder, good repair. Address JOHNSON STOCK FARM, Osceola, Ark.

Wanted—Jersey bull, eight to ten months old. Must be good, and cheap. W. H. MANN, Mannville, Fla.

Scotch Collie Puppies—Bred from the very finest stock. Every dairyman should have one. Address IVY COTTAGE DAIRY, Lancaster, O.

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada 32-52

Exceptionally Low Rates to Denver, Colorado Springs and Pueblo, via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations August 5, 6 and 7, limited to August 31, 1899, inclusive, account of Pilgrimage of Cryptic Masons. Variable routes, delightful scenery. Apply to agents Chicago & North-Western R'y.

The Manure Cellar.

ED. HOARD'S DAIRYMAN:—I notice T. B. Terry, in the DAIRYMAN of July 21st, recommends liquid manure cellars under the dairy barn, for storing the liquid till it can be removed to the field. Many others have advised similar practice. It would seem to one who has not tried the plan, that it would be very objectionable to have a storage of that kind, especially in winter when the barns are tightly enclosed, and the weather conditions make it impracticable to remove it to the fields for quite a length of time. Our great difficulty is to keep up the purity of the barn atmosphere at that season. The importance of saving the liquid manure is no longer a question.

A different plan has worked well with us. The cows stand on cement floors with water tight gutters behind them, about a foot deep. The horse stables are well bedded, and the manure tramped into the cow gutters about three times a week. This absorbs the surplus liquids. The horse and cow manure, by this means, are mixed together, and the liquids as well, and all wheeled to the covered shed. Not only is all the manure thus saved from waste, but the horse manure is prevented from fire fanging, which causes not a little loss by the ordinary method.

Chester Co., Pa. W. G. EMBREE.

Nuisance in City Milk Supply.

ED. HOARD'S DAIRYMAN:—I have read Bro. C. J. Moldenhawer, under the above heading, all that he has written in your paper this year, and felt like punching him when I saw his first communication, and telling him it would be more profitable to him if he would keep his mouth shut, along that line.

And for fear that he may feel called on at some other time, to repeat or write something similar, I want him to know what a brother dairyman thinks of airing such subjects.

I think it fortunate for Bro. M. that his patrons have not read what he has had to say on the subject, or he would find that even his extremely nicely handled milk was not so much in demand as it had been.

To my notions, a dairyman that knows his business will not make public the shortcomings of others in the same business. If he does, his patrons look for the same in his business.

He may say, let them look, they will not find it so. They may not, but if they imagine they do, it had just as well be, so they will not use it. There is more imagination about milk than anything I know of.

They think if Bro. A. puts water in his milk, they all do, and if Bro. A. is not clean with his milk, Bro. M. is not with his.

A lawyer in our city said to me not long since that he used to be very fond of milk, but that he had not been able to stomach it for the last five years, that at that time he saw a cow killed for tuberculosis and saw her udder cut open, and the mixture of blood and milk made him sick. If I were to visit Washington I do not think I would drink any milk, although I might be assured that the milk came from Bro. M.'s extremely nice dairy.

While it is true that all milk is not as nicely handled as it might be, milk is not the only article of food that man eats, that is carelessly handled, not by thousands, and I think that there is fully as much filth drank and eaten by the very best people in the land, in various articles of food and drink, as there is in the worst kept dairy, even around Washington.

I will mention a few of the places that I happen to know, that are not always kept free of filth:—Bakeries, candy shops, cook shops, ice-cream makers, soda fountains, grocery stores, whiskey shops, and even the best of hotels, and then when it comes to city water, —why, I am sure that our extremely nice people of the city often drink water that they would not wash their feet in if they knew just what it was. I will not mention what and how it is contaminated, but every one knows, if they will stop to think.

So, Mr. Editor, do not let them strain so often, at the mote that may be in milk, and leave the dead mule in the reservoir.

Norfolk, Va. F. A. MILLER.

A Study in Milk Production on the Dairy Farm.

Testing Cows at the Farm.

The Wisconsin Agricultural Experiment Station has issued a bulletin (No. 75, June 1899) under the second of the above titles, but it seems to us it might most appropriately have borne the more comprehensive title we give it in this review. While it does, in fact, treat of Testing Cows at the Farm, and proves that this can be done with satisfactory exactness and with, practically, inconsiderable expense, whether of time or money, and thus does away with the excuse that many farmers give for not testing their cows, its more important lessons are that it is optional with the individual farmer to produce milk with profit or at a loss, and in case of profit,

Cow No. 1—(Farm A.) 345 lbs. Butter.

that it may vary from a few cents per cow for the year, to $23.00 or more; even under the conditions now existing on the average farm, without blooded stock or special feeding.

For nearly five years now, the Dairy School Creamery, which is a department of the Wisconsin Agricultural Experiment Station and the College of Agriculture, has been supplied with milk from about 400 cows, on nearly fifty farms located within eight miles of the creamery. For the year ending July 31, 1898, a series of tests were made with the herds of six patrons, who never before kept

Cow No. 24—(Farm B.) 309 lbs. Butter.

any record of the yield or quality of the milk of their cows. In the language of the bulletin, which is written by Prof. Farrington, and under whose supervision the tests were made: "There is nothing abnormally above or below the average creamery or cheese factory patron's outfit on these farms, and the fifty cows which have been tested are undoubtedly a fair sample of those that supply milk to a majority of the factories in Wisconsin."

Cow No. 34—(Farm C.) 360 lbs. Butter.

For reasons stated in the bulletin, the records of these tests, for two of the herds, were incomplete, and they are not included in the published report. Full details of the methods pursued in making the test, are given, but although important and interesting, cannot be reviewed here for want of space. The farmers were paid for the milk on the basis of one-half cent less per pound of butter fat, than the average monthly Elgin market price of butter. At this rate, milk, testing 4 per cent fat would be paid for at the rate of 70 cents per hundred pounds, when the Elgin price of butter was 18 cents. The average price for such milk for the twelve months reported is a fraction over 75 cents per hundred pounds, the average monthly price of butter having been 19.32 cents.

There are several tables in the bulletin, giving a great deal of interesting and valuable information, but the following is the most pertinent for our present purpose:

FARM A.

Cow No.	Age Yrs.	Milked days	TOTAL PRODUCTION LBS. Milk.	TOTAL PRODUCTION LBS. *Butter.	Factory Value of Milk	Value of Fat Per Lb.

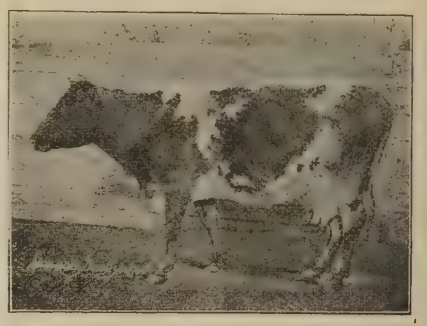
*Calculated by adding one-sixth to the weight of butter fat.

Following is the comment on this table in the bulletin:



"These figures furnish evidence for discussing many questions on which the great majority of creamery and cheese-factory patrons have more or less positive opinions. Probably very few farmers realize that there is so great a difference in the production of the different cows in one herd, as is shown by these records, but they are, undoubtedly, a fair representation of the 840,000 cows that produce the butter and cheese of this state. As already explained, these cows were all measured by the same standard, the weight and test of their milk for a year. About $10 should be added to the factory value of the milk of each cow, as given in the table. This represents about the average value of the skim milk, 5,000 pounds at ten cents per 100 pounds, and a veal calf three weeks old.

The extreme variation in the butter value of the cows on the different farms, is shown in the following table:

RANGE IN VALUE OF ANNUAL PRODUCTS.

REC'D FOR MILK OF	Farm A.	Farm B.	Farm C.	Farm D.
Best cow	$53.35	$58.20	$60.72	$55.49
Poorest cow	28.72	44.83	37.96	39.60
Average cow	36.30	50.00	48.83	44.12
No. of cows in the herd	12	5	12	4

Since each farmer fed all his cows in the same way there is no evidence to show that it cost farmer A any more to feed the cow that paid $53.35 than the one that paid $28.72. But these figures do not mean that cow No 1 is worth $53.00 and No. 9 $28.00; because if the feed of a cow for a year costs $30.00, as shown on page 14, cow No. 1 earned an annual profit of $23.00, but the

Cow No. 8—(Farm A.) 262 lbs. Butter.

farmer lost $2.00 by keeping No. 9. In five years No. 1 would pay $115.00 into the owner's pocket, but if he kept No. 9 during this time a loss of $10.00 must be made up from some other source.

An inspection of the receipts from the twelve cows on each of the two farms, A and C, shows that at farm A there were three cows which did not produce milk enough to pay for their feed. The entire herd only paid a profit of $75.00, and three of the twelve cows paid $50.00 of this amount,

Cow No. 31—(Farm C.) 329 lbs. Butter.

while the combined profit of the other nine cows was only $25.00. In this case three cows earned 100 per cent more money in a year than was earned by nine other cows on the same farm.

On farm C, the twelve cows earned a total profit of $228.00, instead of $75.00, as on farm A, but even at farm C there is considerable difference in the cows. No. 38 earned only about $8.00 profit, No. 37 earned nearly $31.00, a difference of about 400 per cent in the annual butter yield.

Cow No. 37—(Farm C.) 392 lbs. Butter.

LENGTH OF MILKING PERIOD.

A few of the cows tested were such persistent milkers that their owners had some difficulty in drying them off. This was especially true of Nos. 6, 31, 34 and 37. These cows were all among the greatest producers. The cows that were dry the longest time were generally the smallest producers. This is shown by the records at farm A, where several of the cows were dry for three or four months in the year. No. 23 is a notable exception, however, as she was dry about three months, and the value of her milk was nearly $50 for the year."

Prof. Farrington was kind enough to send us some time ago photographs of several of the cows whose records are given in the fore-

going table, and we have selected a dozen representative animals for the illustrations on this page. There are some surprises when we compare the pictures with the records. For example, we can see no sufficient reason why, on Farm A, cow No. 9, should fall so much in the rear and No. 1 come out so far ahead. Our choice in this herd fell on No. 8. It will be observed that this herd made a poor showing, both in the aggregate and the average. The photographs, more than the engravings, indicate that it was not well fed or well cared for. Perhaps No. 1 was the "boss" cow and thereby managed to fare somewhat better than the other.

Cow No. 9—(Farm A.) 171 lbs. Butter.

Farm B shows a much better record, but this is due, in our judgment, to better care and feed, rather than to better cows. No. 23 has the best record, but 22 and 24 did well and we selected them for illustration as average types of the herd. Judging from appearance one would not be likely to have picked 23 for the winner.

Farm C did extra well, on the whole, but the bulletin very properly calls attention to the fact, that six cows in this herd paid 60 per cent of the total profit for the year. On this farm the owner kept a careful record of all grain fed to his cows, and his expenses and receipts are given as follows:

Cow No. 32—(Farm C.) 378 lbs. Butter.

EXPENSES.		
*Grain bought during year		$180.00
30 acres corn stalks, $2.00 per acre		60.00
10 tons clover hay, $5.00		50.00
10 acres good pasture and 15 acres woodland		65.00
Total cost of feed		$355.00
RECEIPTS.		
Received for milk at creamery	$572.00	
Sold 12 calves at $5.50	66.00	
	$638.00	
60,000 lbs. skim milk, 10c per 100 lbs	60.00	
Receipts exceed feed cost		343.00
	$698.00	$698.00

*The grain feed consists of corn and oats, ground together, corn meal and bran, or about 15 tons of grain at $12.00 per ton.

Presumably, all the cows in this herd were fed alike and it is instructive to compare Nos. 32 and 33. Each was in milk the same number of days, and yet, notwithstanding 33's milk tested higher, she fell off $16.29 in gross income, because of deficient quantity. We account No. 32 the best cow in this herd, although her yield of butter is 14 pounds less than that of 37.

Cow No. 55—(Farm D). 350 lbs. Butter.

For so small a herd, Farm D presents a wide contrast in the yields of its best and poorest cow. This difference is so great as to suggest that cow No. 56 was not at her best.

Evidence heretofore collected has convinced most dairymen that a cow coming fresh in the fall will yield more milk than if fresh in the spring. The figures given in this bulletin show that the time of freshening has a decided effect upon the average price of her butter fat for the year. This price for cows fresh in September was 19.2 cents per pound; for those fresh in December, 17.3 cents; March, 17.6 cents; June, 18.6 cents.

We have by no means exhausted, or even so much as mentioned, the different veins of pertinent information in this bulletin. To do so would require reprinting practically the whole of it. It differs from other bulletins on somewhat similar lines, in that it treats of herds not under expert management and not made up of selected animals, though we can scarcely agree with Prof. Farrington that these cows constitute "a fair representation of the 840,000 cows that produce the butter and cheese of Wisconsin." The influence of the Wisconsin Dairy School and Agricultural Experiment Station, located in the center of the section where these farms are situated, has not been without effect in raising the average standard of the cows on these farms. The average yield of butter per cow on these four farms was 281.7 lbs., whereas, in the state at large, it will fall far below this—perhaps not exceed 200 pounds.

Hence the necessity that this bulletin should have the widest possible circulation in Wisconsin and that the surplus of the edition go to inquiring dairy farmers in other states. Prof. Henry writes us that a copy will be sent on application. Address, Wisconsin Agricultural Experiment Station, Madison, Wisconsin.

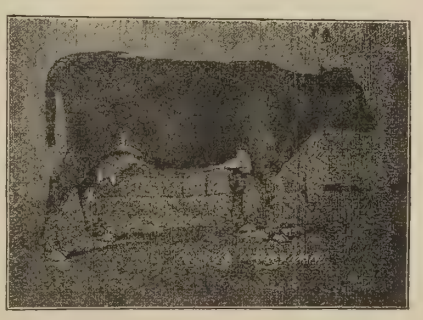
Silos and Ensilage.

ED. HOARD'S DAIRYMAN:—I have used ensilage for ten years, and have fed it to all kinds of stock. Last year a tornado swept over my farm on the last day of July and practically ruined my corn crop. I have two neighbors that are stock raisers, and neither of them got a dollar an acre in value from their corn of about a hundred acres each. My crop was not injured quite as severely as the one, but about the same as the other. On looking the gronnd over, I decided that mine was far enough advanced to make ensilage, and I immediately put up a new silo, eighteen feet in diameter and twenty-six feet high, and filled it together with two others that stood along side of it, one sixteen and one seventeen feet in diameter.

The result was that I carried my cattle through with comparatively little outside feed, while they had to buy hay from early winter until grass came again, and neither one had as large a herd of cattle as I did.

I have used three kinds of silos, one fourteen by twenty-eight and twenty feet deep, one twelve feet wide and forty-five feet long and twenty-two feet deep. These I have discarded because of the difficulties in getting the ensilage out, and the loss at the corners and sides.

I now build a low wall, if of stone, not over eight inches high, if of brick three thickness of brick, using cement to fasten it together. On this, what seems to be a fragile wall, I put staves, using two by sixes, twelve and fourteen feet long. I make the bottom on the inside in shape of a saucer out of clay, letting the earth reach up about two or three inches at the lower end of the staves.



I find that clay is better than cement for the bottom, because it will accommodate itself to the surface, against which it rests, and fill all the openings and interstices, which a hard substance like dried cement will not do. I put on hoops and fasten the ends with pieces of galvanized iron and put in the doors, like a plan sent out by the DAIRYMAN, and for the last two years I have not lost an appreciable amount by decay or in any other way. The silos seem to be practically airtight. Two of my silos have jointed edges, the other two are grooved, and a thin strip

Cow No. 22—(Farm B.) 311 lbs. Butter.

put in the respective grooves in the adjoining staves. The planing mill man where I had my staves dressed, said that he would as soon cut the groove in as to merely joint them.

I can see but little more value in those that have tongues than in those that are jointed; although because of splinters that fly, when lumber, not of the best quality, is jointed, I imagine that those that have the tongues in the grooves are a little superior to

Cow No. 33—(Farm C.) 264 lbs. Butter.

the others. I think a silo about twenty-six feet high is about the right height, although if my conditions were such that if I could have a deeper one without elevating the ensilage more than twenty-six feet, I would prefer it. I shall build another silo this fall, eighteen feet in diameter and I shall build after these last models, as I think these are the best, after seeing a great many that my friends have built.

I find that my cows did better on ensilage than any soiling crop that I could give them, and it is much cheaper than any other feed that I can raise. I plant three different

Cow No. 56—(Farm D.) 260 lbs. Butter.

kinds of corn, so that I can put it in the silo in the same degree of ripeness. I prefer my corn almost ready to cut and shock, just as the ear comes out of the milk state. I have raised corn on the farm that I am running, nine years, and in five of those years I have measured off from ten to twenty-five acres of land to see what the yield was, and in each of those five instances these measured tracts of land yielded over 100 bushels of shelled corn to the acre, one year 110. While most farmers would think that there would be a good deal of grain going to waste by putting it into a silo, I find that in no other way can I get the same value out of my corn field, as I can by putting it in a silo. T. E. E.

Fort Wayne, Ind.

Cultivation of Corn for Conservation of Moisture.

(Press Bulletin.)

A test of relative values of deep and shallow cultivation of corn on the Station Farm, demonstrated, beyond doubt, the superiority of the latter method. Four acres of land were divided into tracts of one acre each, and each tract was cultivated by a different cultivator, the same one being used on each throughout the summer. The same number of cultivations were given in each case.

The cultivators used were the Moline corn plow (Brigadier) to represent the deep style of cultivation, and the Moline spring tooth cultivator and the Superior cultivator to represent the shallow cultivators. In the fall the corn was picked from each acre and weighed. The yield was as follows:

Method of Cultivation.	*Yield per Acre.*
Deep cultivation	59 bushels
Shallow cultivation	68 "
" "	69 "
" "	69 "

The land receiving shallow cultivation was stirred to a depth of three inches, that receiving deep cultivation to a depth of six inches.

Shallow cultivation for corn possesses two advantages over the other method. In the first place by stirring the soil to a depth of only three inches the air does not penetrate so deeply, and it does not dry out to such a depth. A study of the roots of the corn plant show that many of them would naturally grow within three or four inches of the surface, but when the upper layer of soil is dry they cannot obtain any nourishment from this portion of the ground.

Another injury to the corn crop from deep cultivation is the tearing out of the corn roots by the cultivator shovels. By pruning these roots the ability of the plant to secure nourishment is greatly hindered, and the crop injured thereby.

It is very important that the cultivations should be sufficiently frequent to prevent a hard crust from remaining on the ground for any length of time.—Nebraska Experiment Station.

Cow Peas in the Silo.

As I see so much in the papers lately about cow peas, I thought maybe my experience with them as silage might be of some interest. I have been using a silo for eight years—do not believe a man can afford to run a dairy of any size without one—and for the last four years I have used more or less peas in the filling of it; believe it makes a better silage than all corn.

The first year I drilled the peas in with the corn. The corn was tall and heavy, but in some places the peas grew almost to the top of it, making such a heavy, tangled mass that it was a difficult matter to handle it. I next drilled the peas in rows about twenty-two inches apart, and cut them with my mower and put them through the cutter separately, cutting a load of corn and then one of peas, and by the time it was fed out of the silo it was pretty well mixed.

One very great advantage in growing the pea, I think, is that it will enable you to use the same piece of land for growing your silage crop almost indefinitely, which is a very great advantage, as it is important to have the crop near at hand to make rapid work in filling. By growing one-half of the land in corn and the other half in peas, and after cutting it off I run my disc harrow over it and sowed it in rye, which gave me a fine pasture in open weather in the winter for my calves, and several days earlier a bite for my cows; in fact the fourteen acres that I had in this spring grew so fast in April that fifty head of cattle could not keep it down. Then plowing it under and planting back to corn and peas, reversing them (planting one where the other grew the year before), I found my last year's crop the best I had grown without using any manure and only about 100 lbs. of bone dust to the acre on the rye.

Of course in planting equal parts of land there will be more bulk of corn, and it will take a few acres more of land to fill a large silo by using the peas, but I think the other advantages will outweigh this. I find the whip-poor-will pea is the best, as it does not run to vine so much and will bear an immense crop of peas, which makes very rich feed. They should be planted about ten days or two weeks later than the corn unless it is a very large and late growing variety. It takes a large cutter and is heavy work to handle them, but I think it pays.—N. FRAZIER *in Jersey Bulletin.*

Wheat Versus Mixed Farming.

ED. HOARD'S DAIRYMAN:—I hand you, herewith, a copy of a letter written to an inquirer for young bulls, in Western Minnesota, which is self-explanatory, and may be of interest to others in like situation:

"I received your letter in reply to mine offering young Holstein-Friesian bulls, some time since; but the tone of it, and some things you said, caused me to lay it aside for a few words in reply.

"You remark that you are just changing from wheat to mixed farming, and it carries me back in mind to the condition of affairs in Southern Wisconsin, twenty-five years ago, when I began farming on my own score. Then, our reliance was on wheat and hogs; though, of course, we had some considerable stocks of cattle and sheep, and raised other grains than wheat and corn. But we had no creameries, and cheese factories were just being established here and there, where they thought the farmers could furnish enough milk to keep the life in them. Now, the creameries are close together, so that it is an easy matter to get all the milk in, in good condition for the separators, and, although there are three large creameries within four miles of Darien, the creamery of which I am secretary, took in nearly 7,000,000 pounds of milk in June, and set afloat nearly $5,200 in cash, last Saturday, which was pay day.

"I have not seen a wheat field in years; but our sales of other things, such as hogs, hay, barley, cattle, veals, oats, clover seed, and timothy seed come to very much more in the aggregate than our wheat sales ever did in their best days, while we have all the money which the creameries set afloat as entirely extra; and, instead of our lands becoming more and more unproductive, we are bringing them back to their original state of fertility. Our people so value their skim milk for pigs in summer and calves in winter, that they will not support cheese factories, because of its loss, and the general valuation put upon it is fifteen cents per one hundred pounds. The monthly pay day does away with the necessity of long credits in business, making all dealings very largely cash. On a cash basis, or very short credits, our merchants can afford to sell on smaller margins, and do so;while our hired men are more contented, though I think not so well off, when paid monthly.

"The sooner you take up mixed farming, with the dairy prominent, the better; and if you can get ahead of your neighbors by a little time, it will be hundreds of dollars in your pocket later on. At first,you cannot get what we do here out of the dairy department, any more than we could get it twenty-five years ago, but you have all got to go through the transition state, with low prices for your milk, till you get the dairy sentiment properly worked up. Meanwhile, you can be getting together a good herd of cows, so as to be ready to take advantage of the coming change; and to get a good herd, you must start right. It is hardly likely that the average of the cows in your section is equal to the average in the dairy sections, though they might be, and yet be nothing extra, but you must have some good cows, and you may know of neighbors with some good ones, who would let you have the use of them, if you would furnish the bull service, and pay them a couple of dollars or so each for the heifer calves, more than their values as veals, or for raising.

"Then, if you will either kill or veal the calves from your poorer cows, and substitute those you buy from neighbors, you will have a herd of dairy cows in the cheapest way and shortest time, that it is possible to accomplish such a thing. Of course, you will do as you think best as to the steer calves, but dairy form and beef form are hardly found in the same animal, though a Holstein-Friesian grade from a beefy cow comes nearest to the so-called "dual-purpose" animal. I raised a dozen such steers myself some fifteen years ago, weighing an average of 1,450 pounds, at 2½ years old, and selling for something over $50 each, and, considering that they had only the ordinary care of farmers' calves and young cattle, I thought it a profitable transaction.

"In the selection of a bull, the old adage that the bull is half the herd, should ever be borne in mind, for in starting right here you will save yourself much of disappointment and regret in the future. After satisfying yourself that the bull is good individually, you will wish to know all about his breeding, close up. Do not allow yourself to be misled by advertisements so worded that old breeders, after carefully studying them, can not make out the pedigree; for, although you want to know the ancestry of your bull, and will consider it the more desirable in proportion to the great cows in it if well placed, you will wish to know what proportion of the blood of those great cows the bull carries, and whether his immediate ancestors rank with them. You will wish to know what his sisters and half-sisters have done; next, what his sire's sisters and his own dam have accomplished; then, the grandam on each side, and so on back. In order to guage your judgment correctly, you will need to know what a great cow is. Formerly, only such cows as yielded—or were said to yield, for the say-so was the principle part of it—from thirty to forty pounds of butter in seven days were considered great, and they were, of course, quite scarce, since no honest breeder ever had any, but, since the World's Fair and the introduction by the Holstein-Friesian Association of the official test, conducted by the various State Experiment Stations, we have had quite another standard. We now know that those full aged cows giving fifteen pounds, are excellent; those giving seventeen and one-half pounds, very excellent; those giving twenty pounds, great; and those giving above twenty-two and one-half pounds, very great indeed. There are but a few of these latter, and the world's official record stands at about twenty-six and and three-fourths pounds, and is of couse held by a Holstein-Friesian cow. All records published by the Holstein-Friesian Association are of the official kind and absolutely trustworthy; the Jersey breeders are still harping on their victory at the World's Fair, where the Holstein-Friesians were unrepresented, and making private tests of the thirty-odd pound kind."

MALCOLM H. GARDNER.

Darien, Wis.

Canadian Experience With Stave Silos.

ED. HOARD'S DAIRYMAN:—I have had nine years experience with silos; two years with a square silo (not satisfactory) and seven years with the stave silo, a description of which appeared seven years ago in the DAIRYMAN and for which Prof. Henry fell foul of me and threw cold water on that kind of a silo. I am glad to know that they seem to be taking the lead owing principally to their cheapness.

Seven years ago I built the first round silo, twenty two feet in diameter and twenty feet high. Four years ago I built a summer silo, ten feet in diameter and twenty feet high, for summer feeding. Unfortunately last season on the tenth day of July we had a severe frost that reduced my corn crop to such an extent that instead of gathering 180 tons of silage we only had about 125 tons, which was all consumed before pasture came, and although we have had good pasture this year the loss of silage for the summer has entailed a decrease of yield of milk at least 15%.

I have built a modern dairy barn this year, (a description of which I will send you when I have more time), and have taken down the two silos and am using the material to build two others. The only changes I intend making is to increase the height from twenty to thirty feet, and, as to the large one, reducing the diameter. Each silo will be fourteen feet by thirty and will hold about 100 tons each.

In taking down the large silo, the ends of which set on a cedar rim, I was surprised to find the lumber as sound as when it was put in seven years ago. The new silo will be set on a concrete foundation, and will be three feet in the ground, and will be backed up on the outside with cement two inches thick, as high as the surface; the bottom will not have any other covering than what nature furnished. With the aid of silage I am able to keep from fourteen to seventeen cows, milking, and young stock and registered Jersey bull, the total amounting to thirty-four to thirty-six head, on one hundred and twenty acres.

The farm is increasing so rapidily in fertility, that I now do not require to purchase any supplementary feed, changing oats or peas for bran, as required.

How any dairyman can get along without silage is past my comprehension. If he can make a profit without, he should make a competency in a few years with it. I think, (and I know) the summer silo is of more value now than the winter one, and no dairyman should be without one. Better use less silage in the winter, and keep a reserve for the summer. J. E. G.

Ontario, Canada.

St. Lambert Jerseys, all ages, both sexes. Some from **tested cows** at low prices. **W. J. HUSSEY,** Mt. Pleasant, Ohio.

THE Evergreen Farm Herd of A. J. C. C. Jerseys is now headed by St. Lambert of Brodhead, whose pedigree is unequaled in the northwest. We should be pleased to have any one in want of Jerseys to write us for catalogue, stating just what is wanted. N. N. PALMER & SON, Brodhead, Wis.

GREEN PLAIN HERD
POLLED JERSEY CATTLE
Recorded stock FOR SALE. Inquiries promptly answered. **W. H. FORBES, Clifton, Ohio.**

Diplomas Combination 39962.

New York Farm and Dairy Notes.

The Farmer's Vacation,

ED. HOARD'S DAIRYMAN:—At this time of the year, when business and professional men are taking a vacation, it may be well for the farmer to think about it, and if possible, plan to take a few days for rest and recreation. I think there can be no doubt but what the farmer needs a vacation that will afford him a change from the usual routine of life, and a rest from his work, but it is a question with many farmers whether it is possible for them to take such a vacation.

I think that most farmers can plan to take a week or two of rest after their haying is done, and it will pay them to do so, instead of continuing to work all through the hot weather we usually have in August. I think their vigor would be so renewed by the rest that more work would be accomplished. How shall a farmer take his vacation is not an easy question to answer, but it must depend on his circumstances.

Some farmers can afford an expensive summer outing, but the great majority cannot, and writing from my own experience, I wish to tell the latter how a vacation can be taken at home with but little expense. I really think the vacations which are taken at home are the most profitable. I do not say that a journey to some place which one desires to visit is not sometimes desirable, in that it breaks up the old routine of life, and affords new objects to look upon, and to think about, but for many, the expenditure of energy such a journey calls for is too great after the hard work on the farm, and their income is not sufficient to justify the expense.

I will suppose that a farmer has been making his plans, and has his work in a condition, so for a week or two he need not do anything but care for the live stock, and even this work he can sometimes leave for others to do. Just how to spend one's time will depend on one's tastes. Some will wish to take the most of the time for reading, playing croquet, tennis, etc. Others will wish to spend a part of their time driving, visiting friends or some points of interest that can be reached in a day or two from home. One may spend a day in going on some of the cheap excursions that the railroads provide at this time of the year. In whatever way the vacation is spent, it should be spent in a way that the farmer will be in a better condition to resume his work when it is over.

REPAIRING MANURE GUTTERS.

During the early fall, when the cows can be kept on the pastures, is a good time to make the manure gutters in the stable so tight there can be no waste of the urine. I have just repaired a gutter in my stable, that was not perfectly tight. I have a lined plank floor, and I supposed I could make the gutters tight by lining them with matched, pine lumber, but I was mistaken. They were made by a good carpenter who made all joints as tight as possible, but some of the liquid would soak through the joints. I was not satisfied until they were perfectly tight, and I have had them plastered with cement. The whole gutter, bottom and sides were plastered, but boards were fitted on the sides of the gutter, after plastering them, to hold the cement in place. These may be removed when the cement has become perfectly set, or they may be left, as one chooses. The cement lining in my gutter has so hardened that it could not be better if it was cut from solid stone. The expense of fixing it was small, it is perfectly tight, and I think it will last many years without repairs, but if the cement should wear so thin as to leak, it can be cheaply repaired.

My observation of stable floors has shown me that there are but few gutters made of wood but leak more or less, and the leaks are mostly in the joints at the bottom of the gutter. If the gutter is not wide enough to admit of plastering the sides, a layer of cement on the bottom of the gutter, two inches thick, will usually make them tight.

We are told that the urine represents sixty per cent of the value of the manure, and we certainly cannot afford to let it run through the stable floor, as many farmers do and then buy commercial fertilizers. For those who wish to work towards a plan of more intensive farming, the great need is manure, and no one can afford to buy fertilizers, until he has saved all that is made on the farm.

If you have manure gutters which leak, there is no question but what it will pay to fix them, when the cows can be kept on the pastures until the cement gets hard, even if you must hire the work all done. If you can afford to, put in a cement floor, and plank it where the cows are kept, but if you can do no better, plaster the old wooden gutters with cement.

COWS THAT WILL NOT BREED.

Occasionally there is a cow in the dairy that will not breed. If the cow has been a good one, or is a pure bred, and for that reason valuable, one is sometimes tempted to keep the cow a year or two, hoping she will get with calf. I have a Jersey heifer from pure bred registered stock that dropped her last calf one year ago last spring. Since then she has been served with the bull at different times, but she does not become pregnant.

I would like the opinion of our veterinary scientists on this problem, and I think the opinion would be of use to others, what they would do with such a heifer. The one referred to is three years old, and seems to be perfectly healthy. Should such a heifer be fatted for beef, or kept a year or two longer to see whether or not she will breed?

Delaware Co., N. Y. W. J.

How the French Teach Agriculture.

France spends nearly a million dollars a year for the advancement of agriculture. No doubt this large expenditure of money has much to do with the wonderful improvement that has been made of recent years in French farming. Not only have farm methods been improved, but the position of the farmer socially and politically as well. Agricultural teaching is now given in France in seven different stages or degrees. First, there is the superior instruction of the national agricultural college; second, the national schools of agriculture; third, the practical schools of agriculture; fourth, apprenticeship schools, where boys and girls are taught all the mysteries of general farm work, fruit growing, dairying, silk culture, epicul. ture, and fish culture. Then there are five mixed schools, with professors of agriculture and agricultural chemistry; and, sixth, instruction in the fields, for all of these schools have lands attached. Seventh, France has carried to great perfection her experiment stations, which are doing a work similar to what our own stations are doing.

Thus the farmers of all degrees can find a school where their children will get the knowledge they require to fit them for any kind of farm work. By this means those engaged on the soil are kept abreast with the best and latest practice in agriculture, and are enabled to see and learn such things as tend to the improvement of their condition and industry.—*Northwest Farmer.*

CONCERNING OUR ADVERTISERS.

Mr. J. D. Thompson, superintendent, writes us under recent date, that the name of the Hickory Herd Jerseys has been changed to Arden Herd. Mr. H. N. Higinbothom, proprietor of this herd, is sparing nothing to make it one of the best in the country. We hope soon, to illustrate one or two animals from this herd, and expect to show our readers something unusually fine.

The fundamental principle of good farming is the maintenance of the soil's fertility; and it is shown by years of experiment, that with no fertilizer can such good results be produced, and at so slight an expense, as with stable and barn yard manure, rich in the very elements that the crops fed to the stock have drawn from the soil during the preceding summer.

It is a lamentable fact, however, that the vas-bulk of farm manure does not effect more than fifty per cent of the good it is capable of doing. The value of manure depends entirely upon its care and distribution. If it is thrown into an open yard from whence its valuable elements are washed away in the rains and burned away by the sun, or if it is dumped in the fields in piles, it is doubtful if even twenty-five per cent of its most valuable elements are ever available for plant food. Every year demonstrates that barn yard manure spread by hand utterly fails to give the results that the good farmer should expect from so valuable material; the reason is, that all plant food is taken up only in liquid form, and the coarse manure cannot be dissolved in time to be taken up by the plant when the food is most needed. It stands to reason, as it has been proven by experience, that the finer the condition, the more thoroughly pulverized the manure is when applied, the better it is for both the crop and the soil. The more unevenly the manure is applied, the more certain is some of it to waste.

This fine condition and even distribution can only be attained by mechanical means. The Kemp Manure Spreader is the only machine which fully answers this purpose. Every farmer should have the book on "The Problem of Fertility," published by the manufacturers of this spreader, the Kemp & Burpee Mfg. Co., Syracuse, New York. It is one of the best treatise on the care of manure, that we know of, and is offered free by the manufacturers, to the readers of this paper.

Producing, Retaining, and Controlling Flavor in Butter.

[Paper read before the Kansas State Dairy Association by PROF. G. L. MCKAY.]

I am always pleased to meet the Kansas dairymen. Your up-to-date dairy meetings and your western rush and energy, give us that live east of you, new impetus to go back home and do a little better work. In this great western butter belt, the making of fine butter is not confined to any one factory, township, county or state. Your chances are as good in Kansas as anywhere in the west. It is true that your climate is a little warmer in the summer months than some of the other states, but with your refrigerator machines and a little more education of your patrons in the care of milk, this need not give you any trouble. I have great hopes of Kansas becoming one of our greatest dairy states.

The most important single quality of butter is its flavor. This is not to be wondered at, as flavor counts from 45 to 50% of the total in scoring. Everything that affects flavor is of great importance to the butter maker. It is only within a few years that the theory of butter flavor has become partly understood. The effect of food on flavor is a question not yet settled. We do know that when cows have access to leeks, turnips, onions, cabbage, potatoes, etc., that the milk has very offensive odors, which are transmitted to the butter, unless the milk or cream has been pasteurized. The obnoxious odors seem to evaporate during pasteurization. Some maintain that the germs of bacteria, that produce the disagreeable flavor, get into the milk from external sources. I am not prepared to substantiate either of the theories that I have just mentioned, that the food affects flavor or that it does not.

It is true that we have conducted a series of experiments at the Iowa Station during the winter of 1895 on the effects of food on the flavor of butter without finding any marked difference, except where turnips or cabbages were fed and the butter was made from raw cream. From these and other experiments, I have come to the conclusion that the food consumed by the cow does not affect the product as much as is generally supposed, and that the fine flavor of the butter is argely a product of fermentation. Another quite common theory is that the milk, from strippers, or from cows well along in the period of lactation, is responsible for the low flavor of butter during the winter months. It is true that as the cows advance in the period of lactation, the fat globules become smaller and the milk becomes more viscous, thus rendering it difficult to churn. Frequently the food consumed by the cow is of such a nature as to produce hard butter. At this period, we not only experience great difficulty in the separation of the milk, but also in the ripening and churning.

As the cow approaches parturition, she is inclined to be more excitable, which in some cases affects the quality of her milk. We succeeded in making butter at our school, from the milk of cows that would average near seven months in the period of lactation, that scored ninety-seven by some of the best experts in the country. These cows were carefully looked after, and the cream was ripened with a good starter. This would also indicate that flavor was a product of fermentation.

If any one has a theory and can demonstrate to the public that it has merit, the public will usually accept it for what it is worth. Some theories have fallen flat, as they would not stand a practical test.

I believe that a high flavor of butter or quick aroma, is due to the breaking up of the milk sugar in the process of ripening, and is possibly the product of a series of germs.

If we churn cream sweet, no matter how well the cows are fed, the butter will lack flavor and our losses of fat will be great in the buttermilk. If cream is allowed to ripen too much, we get what experts term sour butter, or what I would term almost a rotten egg flavor. From these facts we must consider that cream ripening is a very important point in butter making. The common theory used to be that when cream assumed a smooth, granular appearance, it was fit to churn, but this is not always correct. I will say, however, that when cream is ready to churn, it will always have that smooth, granular appearance. I presume that some of our prominent buttermakers in the past have observed the condition of their cream when they have made some extra fine butter, and have found it to have a nice, smooth, granular appearance, so this has been handed down to us as a test, when cream was ready to churn. I have seen cream have this same appearance when it was not near ripe enough to churn. In natural ripening the fermentation is due to the growth of a variety of organisms that gain entrance to the milk and cream from the time the milk is drawn until the cream is churned. When cream is ripened by a starter, we attempt to control the fermentation by adding a large number of bacteria, of a kind that we expect will give the desired flavor. The majority of the lactic acid species are evidently flavor producing germs. Prof. Eckles, of our school, has made many bacterial analyses of cream when ready to churn, and he found the percentage of acid bacteria was estimated to be between ninety and ninety-five in the best cream. He found one case where the per cent went down to 81. This was very poor, tainted cream.

The butter that scored the highest on flavor at Topeka, at the National Convention last year, was made at our school, and the cream showed 92% of acid bacteria.

Many of you have observed, no doubt, that a great many butter makers make good butter in the summer months, but are not successful in the winter months. Now there must be some reason for this. Most of th milking is done in the open air during the summer months, and the germs that get in the milk are not as injurious to flavor as those that come from the stables.

Possibly the reason that pasteurization has become so general in Denmark, is that their cows are stable fed most of the year.

Prof. Eckles has made a number of tests of milk coming in from different patrons, at different times of the year. The results he will publish later on in a bulletin article. Of 100 samples taken March 5th, only 12.5 per cent showed pure acid flavor, 48 per cent impure acid flavor, 39.5 rapid decomposition of curd. April 8th, he found pure flavor 50 per cent, impure acid 26.7, rapid decomposit on of curd 23.3. On May 10th, 90 per cent of pure acid flavor and 10 per cent impure. On July 13th, 90 per cent of pure acid flavor and 10 per cent impure. Thus it will be seen that during those months that milking is done outdoors the cream as well as the butter is better.

We found that a great portion of our milk last winter seemed to contain bacteria that had the power to coagulate the milk without souring it.

I think that possibly a lot of the low scoring at the National Convention was due to this condition. During the time our boys were making butter for that convention, one of them, in his great desire to get an extra good starter, bought the milk from a friend of his who had a number of cows, and had nice clover hay for them to eat. This young man went to the place and did the milking himself, after carefully washing the udders. The milk was thoroughly aired as soon as drawn. Every precaution had been taken to keep the milk in good condition, yet when it soured it had about as disagreeable a flavor as I ever ca ne across. Not being satisfied with the first lot, he repeated the whole experiment for another starter, but obtained the same results. The only reason I can give for this is that the sta le where the cows were kept was a poor, badly ventilated building with low ceiling, and the bacteria that got into th milk from the barn were undoubtedly of the putrefactive kind. In selecting milk for a starter, the fermentation test would come in very useful. A good starter should sour with a pleasant acid taste. It should coagulate solid without any pin holes. The amount of starter that should be used will depend somewhat on the condition of the milk received. If you have a good starter, do not be afraid to use a good per cent in winter months. I would advise from 15 to 20 per cent.

The temperature at which cream is ripened is not a very important factor in making good butter. From 60 to 90 degrees F. will give very good results. If I were going to specify any set rule, I would say 65 degrees for summer and 75 degrees for winter months. It is not the temperature at which you ripen, but the degree of

Beware of Cheapness.

BEWARE of the butter color that an agent claims to be *"just as good"* as W. R. & Co.'s Improved, but which he offers at a cheaper price.

There is not and never has been a color *"just as good."*

Why should any one be obliged to offer a color at less price if it is *"just as good."*

While cheap colors may be cheap in price, they are expensive to use.

acidity to which you ripen, that is the most important point to observe.

I think it is possible for any butter maker who thoroughly understands his business to score from 95 up, and do it every time. In fact, I think I could raise that one point and be within the limit. To demonstrate this more thoroughly I will mention the Genesee salt contest, which has been going on for six months in Chicago, and has just closed. Many of the butter-makers in the United States have been competing. The sweepstakes went to M. W. Ashby of Hazelton, Iowa, with an average of 97.79⅙. He was one of our students in the class of 1894. The second place went to Mr. C. L. Passmore, of Iola, Wis., with an average score of 97.62½. He is a nephew of Gov. Hoard, so comes of dairy stock. He was a student of our school in the class of 1898. Another one of our boys from the class of 1895, Louis Schack, made an average score of 97.41⅔. Still another from class of 1894, August Johnson, of Bancroft, Iowa, had an average score of 97.18¾.

To this I might add the record of three of our boys at the National Association last winter, who were in the final eleven that were picked out from which to select the sweepstakes. These facts show what trained butter-makers can do.

We endeavor at our school to ripen cream so as to contain about .64 of one per cent of acid. This I mean for 30 per cent cream. If you are using the alkali solution, this would mean that it would take 36 c. c. of the solution to neutralize the acid in the 50 c. c. of cream used. When you go to .70 of one per cent you are approaching the danger line. If good starters are judiciously used, I do not think that you will have any complaint about winter conditions. If you have a patron that always brings you good milk, and you find that it will sour with a pleasant flavor, you may be sure that you have the right kind of bacteria present. Milk of this kind you can put in your cream vat without separating, that is, you can use a few cans of such milk and then separate your cream heavy enough so that you will have the desired per cent of fat. We used this method in the winter months and found it to be a great benefit in helping the flavor of butter.

One prominent bacteriologist has said that after natural starters have been used a few times, they become pure cultures. We have found the Douglas culture to make an excellent starter. Our Mr. Eckles has a culture that has given fine results. In fact one lot of butter that was made from pasteurized cream, and ripened with this culture, scored perfect in England. The culture is of the acid species.

I do not wish to convey the idea that feed has no influence on the composition of milk. I believe that the utmost care should be given by the patrons to provide good, succulent food and clean water during the summer (and winter when it is possible) months. The patron should try to get his milk to the creamery in the best condition possible. Then it is the duty of the buttermaker to make the finished product. It is impossible for a workman to produce fine goods in any line of work, where the raw material is faulty.

Boys, keep your creamery in such a condition that you will not insult the intelligence of your patrons by asking them to bring good, clean milk to a dirty creamery. I have been in the dairy business twenty years and have conversed with hundred of patrons, both in the east and west, and have never met one who did not admire cleanliness around the dairy building. It is always easier to lead patrons than to drive them.

One more important point in which a buttermaker should be posted, is scoring. I can not understand why a buttermaker, that will score ninety-eight or ninety-nine in one contest, will allow butter to go from his creamery to another contest, that will score down to ninety or near that point. A buttermaker should know good butter when he sees it, if he expects to make a success of buttermaking.

Possibly some of us at the dairy schools have been a little careless in not requiring more scoring to be done by the students.

Curing Cowpea Hay.

I find many farmers, while they recognize the great value of cowpeas for hay, do not raise them because they have found them so hard to cure without the loss of nearly, if not quite all the leaves, which are certainly the best part of the hay, except the pea itself. Now I find the pea hay the easiest cured of anything in the hay line I have tried, and that too without the loss of a single leaf or pea.

Take some little poles about three inches in diameter and twelve feet long; set them at convenient distances apart in the field, and about two feet in the ground. Take two bits of board, two feet long, and two or three inches wide, nail them across the pole about two feet from the ground, crossing each other at right angles to hold the peas off the ground and allow the air to circulate freely under them. Cut your peas when dry, no matter whether the sky is clear or cloudy, and without waiting for them to wilt stack them around the pole on the boards, making the stack small in diameter—not more than three feet—and as high as you can reach with the fork. Place some crab grass or anything that will shed rain on top, and your peas, rain or shine, will cure out as bright and sweet as can be.

In two or three weeks, lift pole, peas and all, place them on the wagon, take them to the barn, slip the pole out and mow them away.

By stacking the peas before wilting they retain all the leaves and peas, and by lifting pole and all to cart them to the barn, you do not disturb them, and do not rattle them off.

The vines being coarse, and the leaves thin, if the stack is kept small in diameter, no matter how wet the season is, the air circulates through them enough to cure the peas perfectly.

Where barn room is scarce, I have left them in the stack all winter, and though somewhat weather stained, horses eat them with relish.

I think anyone, who tries this method, will find it so simple and effective that they will raise pea hay because it is the easiest hay made, if not because it is the best.

If the weather is rainy when you commence your stack, have a fork full of crab grass handy, then cut peas and stack till a minute before the rain actually falls, then cover your partly built stack till the rain is over. As soon as the peas are dry enough to cut again lay off your fork full of crab grass and complete your stack. It never gets so rainy here in Florida that we can't cut peas and cure them beautifully.—F. A. BUCK, in *Southern Ruralist*.

The cut is after an old painting of a man gambling with Death with his life as a stake. Behind the man stands his good angel striving to save him.

This game with life as the stake is the every-day game of men and women. Behind the player stands the good angel Nature, striving to preserve the life. Even when the game is almost in Death's hands, the man who turns to Nature and lets her help him may yet save himself. Medical science knows this, and its highest authorities affirm that the utmost medical skill can do is to help Nature.

The great success of Dr. Pierce's Golden Medical Discovery in curing wasted bodies, weak lungs, and obstinate and lingering coughs, is based on the recognition of this fundamental scientific truth. "Golden Medical Discovery" supplies Nature with body building, tissue repairing, muscle making materials, in condensed and concentrated form. With this help Nature supplies the strength to throw off diseases of the lungs, heal the sick stomach, re-establish the digestive and nutritive organs in sound health, purify and enrich the blood, and nourish the nerves.

If your dealer offers something "just as good," it is probably better *for him;* it pays better. But you are thinking of the cure not the profit, so there's nothing "just as good" for you. Say so.

In a letter received from A. D. Weller, Esq., of Pensacola, Escambia Co., Fla. (Box 544), he states: "I have, since receiving your diagnosis of my case as stomach trouble and liver complaint, taken eight bottles of the 'Golden Medical Discovery,' and must say that I am transformed from a walking shadow (as my friends called me), to perfect health. I value your remedies very highly and take pleasure in recommending them to any and all who suffer as I did. Four months ago I did not think to be in shape to assist our 'Uncle Samuel' in case of hostilities, but thanks to you, I am now ready for the Dons!"

Dr. Pierce's Common Sense Medical Adviser, In Plain English; or, Medicine Simplified, 1008 pages, over 700 illustrations, paper-bound, sent for 21 one-cent stamps, to cover cost of mailing *only*. Cloth-bound ten stamps more. Address Dr. R. V. Pierce, Buffalo, N. Y.

ECONOMY

How much is your time worth? How much do you value your strength? Is your money worth saving? These questions will all be answered to your entire satisfaction if you use

GOLD DUST Washing Powder

in your cleaning. It will do your work in half the time, with half the labor, and at half the cost of soap or any other cleanser. It will make your housework easy and save you many an hour of worry.

For greatest economy buy our large package.

THE N. K. FAIRBANK COMPANY

CHICAGO ST. LOUIS NEW YORK BOSTON

A PAIR OF HANDS AND A PAIR OF HORSES Are all that are required to Operate a Deering Corn Binder.

The Deering Corn Binder affords the best plan for harvesting corn with economy and expediency.

The Deering Corn Binder alone handles corn on the practical, **horizontal** principle, as a grain binder handles grain.

The Deering Corn Binder has a butt adjuster with great scope of adjustment for handling long or short corn.

The Deering Corn Binder has **Roller** and **Ball Bearings** and less draft and neck weight than other corn binder made.

The Deering Corn Binder.

The Deering Corn Binder has all levers within easy reach of the driver.

The farmer who gets his corn from field to shock or silo with the smallest outlay of time, and with the services of only **A Pair of Hands and a Pair of Horses** is the farmer with a **Deering Corn Binder.**

GEORGE ERTEL CO., QUINCY, ILL.

Packing Dairy Butter.

A problem which puzzles many of our good dairy butter makers today, is how to put up their butter for market in such a way that it will bring the price its merits.

The style and size of package depend upon the market. Where one is obliged to take their butter to a grocer, the gallon and half-gallon crocks are usually preferred. If one has private customers, it depends wholly upon the quantity used. The gem paper packages are light, substantial, and reasonable in price, ranging in size from 1 to 20-pound packages. Where you ship to large grocers or commission houses, the 60-pound white ash tub is desirable. A very good packer for putting the butter in small packages can be made by taking a common wooden potato masher, sandpapering until it is smooth, scalding and cooling. For the tubs one needs a packer such as those used by creamery butter makers.

Before putting butter in crocks, be sure that they have been thoroughly scalded and cooled. Never use crocks which have held anything but good, pure, sweet butter; as lard, yeast, pickles, or, in fact, almost anything will affect the glazing of the jar enough to taint the finest of butter, if it is left in a jar any length of time. In packing, only put in small quantities at a time, and press down firmly, so there will be no pools of brine; continue in this manner until the butter is rounded over the top of jar. Even the top by taking the ends of a piece of twine (which has been wet) in both hands, holding it close against top of jar. With a sawing motion draw across, then holding jar slanting over bowl or churn, carefully lifting the upper edge of butter from jar with ladle, the air will get under the layer, which will drop off, leaving an even surface, which looks much nicer than when smoothed off with a ladle, which is apt to give a salvy appearance.

Place on the top a circle or cap of butter cloth. (These circles may be procured of any dealer in dairy supplies for a few cents per thousand in sizes to fit any package.) On top of cloth put an even layer of nice, clean butter salt, over which sprinkle a little water, and you will have an air tight crust. Cover this with fresh, clean, manilla paper; fasten on by passing twine below rim of jar two or three times and tying with single bow-knot. Trim paper evenly from one-half to three-fourths of an inch below twine, and you will have a package which will find ready sale.

Mark your package with name or private mark, always the same, and in a manner which is not easily imitated, as I have known grocers to go so far as to write the name of some good butter maker on a jar of any butter they happened to have in order to make a sale.

It does not take long for a good butter maker to gain a reputation in the circle where the goods are consumed, and after a few trials the goods are called for by name or mark, and the customer does not find it necessary to have the butter opened for inspection.

If, by accident, you happen to have a poor lot of butter, tell your dealer and let him sell it for its value. Don't run the risk of losing your hard earned reputation of a good butter maker, for the few paltry cents gained by palming off a lot of poor butter under your regular mark. If one has not been fortunate enough to secure regular customers, at a good fair price, and is making a sufficient quantity to ship, it is much less labor, and more satisfactory to send it to some good, reliable commission firm. Use the best white ash sixty-pound tub, thoroughly washed, scalded and soaked in brine, to prevent mould. Always line with good parchment, which it is also advisable to scald and brine. After the tub is neatly lined, pack and even off same as the jars, turning the parchment (which should be left above top of tub about three-fourths of an inch) over the butter, laying in small pleats, putting the cloth circle over the parchment, and covering with salt. Fasten the cover of tub down with three tins placed at an equal distance apart on the cover.

In fact, do not neglect any little thing, no matter how trifling, which will add to the neatness of the package, as neatness in this respect is just as essential as in the manufacture of the butter, and there we know it is one of the important factors. Remember that it is the outside of the package which the consumer sees first. I never realized until a short time ago how many good butter makers there were who were careless in this one respect. Perhaps by mentioning one or two cases, the reader will not think that I am a crank on this subject, or as I have been told that there was too much red tape about my butter making. While in a grocery store not long ago, an old gentleman came in with fifteen pounds of very nice butter in prints, wrapped in hand towels. The dealer offered him 2½ cents per pound less than they were giving for butter in crocks. The old gentleman was quite indignant, but was told that they had no place where they could keep print butter free from taint. After the old gentleman went out, being a little curious over the butter, I watched to see what was done with it. The dealer took it from the towel, placed it on a platter, covered it with clean, fresh-looking paper, called an errand boy, and sent it to a hotel near by, remarking to me at the time that Mrs. So and So had left an order for good butter, and was willing to pay a little extra. I knew that he had refused to pay within 2½ cents as much as crock butter was bringing only a few minutes before. As it takes so little for an excuse to drop on the price, it stands us in hand not to leave any show for the excuse. Never use any cloth about butter, which has the suspicious look of coming from some worn-out garment.

While waiting at the depot, my attention was called to a lot of jars piled on the platform. On inquiry I found they contained butter, which surprised me very much, as out of fifteen or twenty jars not one of them was tied up neatly, and they were to be shipped twenty-five miles. I don't think any of them having paper over the top had anything but newspapers, and on one there was just a thin cloth between the printer's ink and butter. The taste of the ink would, in a short time, permeate the whole jar of butter. Many of them had large, coarse cloths. some even faded-out calicos over the top, and not one of them trimmed off, but corners and ravelings flying as the wind blew them. Please don't think that carelessness is confined to the dairy butter makers. Far from it.

While at the dairy convention last December, judge of our surprise upon lifting the covers of some of the creamery butter tubs to find the salt fairly black, where a dusty cover had been put on. Others hadn't any salt on the cloth cap, while on many the parchment side lining was left from two or three inches above the edge of tub, on some the covers were put on so that the lining was below the edge of cover; on others it was crowded down in rolls on top of salt. While many of them were left about three-fourths inch above tub, folded neatly over the edge of the butter, being laid in tiny pleats so that it would set smoothly. Then the cloth cap with an even layer of salt on top. Any butter maker, who has any interest in his work, could see at a glance the difference. Some say we don't know how. Then ask. If you cannot find out at home, ask *The Farmer* and you will surely get an answer. If still in doubt, read Gossip in the Butter Stores, by Man on the street, in New York Produce Review. If your butter is not selling at the highest price, you know there is something the matter.

Winter Crops

perish when they lack nourishment. Liberal fertilization insures the vigor necessary to resist winter killing.

Potash

Phosphoric Acid and Nitrogen in well-balanced proportions, are what they need.

Many times you will find it in the packages.

If you are shipping to a commission house write the firm for particulars; most of them are only too glad to give such help, if one asks for suggestions and they see that you are in earnest.

If you have a firm which gives you good prices and prompt payments, don't, for the sake of experimenting, or for some trivial expense, make a change. Exercise a little patience, as it takes some time for a firm to determine whether you make a uniform article or not, and you cannot always get a premium in a few weeks, but after your reputation is once established your goods are always in demand.—*The Farmer.*

To Produce Three Hundred Pounds of Butter.

How much milk, of what quality, would you expect a heifer to give the first year in order to promise to be a three hundred pound cow? J. F. P.

Barnston, Que.

A heifer that gives, with her first calf, milk in sufficient quantity and of a quality to make two hundred pounds of butter within twelve months, will be very likely, with proper care and feed, to reach the three hundred pound limit at maturity.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

LUMPY MILK.

I have a cow that calved about three months ago, whose milk from one teat has chunks in it. They stop the milk fo a second and then come out. It began two or three days ago and at one milking since, it was all right. J. F. P.

Barnston, Que.

ANSWER.

Immediate full dose of physic and repeat in five days or so. Give two teaspoonfuls of nitre each morning for ten to twenty days. If needed, use gentle massage daily upon the head of the teats. You state what the matter is yourself. The causes are many and widely different in many respects; quite often it is the result of acrid matter in the pasture or other food; quite often the result of hard milking; jerky milking, etc.

STOMACH TROUBLE.

We have a two-year-old heifer that calved this spring, and did well for about ten days. She then commenced to cough and refused to eat much of anything, and did not chew her cud only now and then, and everything she did eat seemed to physic her, and she run down, and is very poor. I consulted a veterinarian, and he gave me a tonic; said it was indigestion. Well she got some better, so she goes to pasture and eats grass and oats and peas very well, but refuses her grain altogether, and milk is nearly dried up, and is very dull most of the time, but cough has ceased. O. S. F.

Mayville, N. Y.

ANSWER.

I think the veterinarian was correct. I believe she is afflicted with some form of stomach trouble, not ordinary indigestion. Give her one scruple of nux vomica, three drams of golden seal in 1½ ozs. of *old* whiskey and 3 ozs. of cold water each morning for three mornings, then wait three mornings, then repeat as before, then wait seven days, then repeat twice, again wait one week, then give one last dose. If this does not seem sufficient, repeat the dose for a few times, *intelligently.*

NOSE BLEED.

One of our cows came in from pasture the other morning, stopped at spring for a drink and when she reached the barn, blood was running from both nostrils. In a short time large clots of blood and what appeared to be part of lining of the nose came out; the cow (usually very quiet) rushed about, butting at the other cows, and rearing high in air, also kicked at stomach and threw the head from side to side. The bleeding subsided after a day or two, but a quantity of mucous came from the nose for quite awhile. The animal is probably in good health now. Was it probably due to some mechanical injury, or is it some disease that will return? A. J. U.

Valley Mills, Ind.

ANSWER.

By your description I judge the cow did receive some severe concussion about the head, I think in the frontal bones. This would seriously interfere with the nasal sinuous passages of the nose and develop, as you state. I don't fear reocurrence. Apply again if any fresh attack occurs. Don't wait.

MANGE—ESCUTCHEON.

My cows have dry, bare places around eyes, on head and body in places, looks like mange or seed warts, but in some places the hair is off three inches square.

Would like also to know whether the escutcheon on bulls is of any importance? Some run up part way and some not at all. How would it be on their heifers?

Eureka, Cal. H. E. A.

ANSWER.

Scabies, itch, mange, etc., all one. Thoroughly wash in hottish water and tar soap. Then when dry, sponge over with the Tilden's bromo chloralum, one to eight of water. Use liberally twice in an hour. Then thoroughly rub in pyroligneous acid, ten ounces, oil of tar, half an ounce, fish oil, 20 ounces, thoroughly shake before using. Rub in twice a day for a few days.

I would not refuse, otherwise, a good bull because he had, or had not a good escutcheon.

BLINDNESS—ESCUTCHEONS.

My neighbor had a horse die about a month ago. She was affected with a blindness, though she had good eyes. She would go into a gully and not see it; you could turn her one way and she wouldn't turn to the other side at all. He cut her open and thought she had some water about the brain that ought not to have been there. He had a hog pen in about four or five steps of her stall, that was very muddy and offensive. His hogs were fed on skim milk. Could the manure from the pen have diseased the horse, or what do you think was the matter with her?

On page 237, May 5, J. J., of South Hamilton, N. Y., says he places the most reliance on the escutcheon theory in judging cows. I wish he would tell us if he can tell a rich milker by the escutcheon, and whether all breeds of cows have the same shaped escutcheon. D. E. L.

Roper, S. C.

ANSWER.

Hog pens, especially in a filthy condition, have no place near horses or cows. Yes, such a condition of filth can and does affect eyesight and many, almost every condition of health.

The escutcheon is a fad, and the part has nothing to do with the value of a cow, as a good one. I have seen good cows with good and well developed escutcheons, and some of the poorest cows I have ever seen had a fine, distinct escutcheon.

EYE DISEASE.

My cows and heifers commence running water at the eyes, then a white speck commences to grow over the sight of the eye, continuing to grow until they cannot see at all out of the eye affected. A. B.

Pingree Grove, Ill.

ANSWER.

Read the above similar case, and act accordingly. These two seem identical in all the symptoms.

ABORTION.

In this week's issue I see an article copied from an English paper, that I thought from the headlines was going to tell us how to take care of a herd of cows when they were affected with epidemic abortion, but after reading it through, I knew no more than I did when I began, except that one man had been successful by using injections. If you could let us know what he used and how he used it, I have no doubt many of us would be glad to know the particulars. I have a herd of nearly a hundred cows, and within the last six weeks four of them have aborted when about seven months pregnant. As they stand near together, I am a little bit uneasy about the matter. I have sprayed the inside of the barn thoroughly, with a wash of lime, containing about three per cent of crude carbolic acid.

A CONSTANT READER.

Fort Wayne, Ind.

ANSWER.

Enzootic abortion is quite often the result of carelessness in not disinfecting and burning or deeply burying all aborted matter. The vagina and all the hind parts ought to be thoroughly washed and then disinfected with Tilden's bromo chloralum, one to eight of water, used liberally; there is no better or safer deoderizer and disinfectant. So-called carbolic acid *has caused* many abortions within my own knowlege; cows abhor it. I don't know about your injections—do know all such sure remedies are suspicious at least, and far from trustworthy.

IMPERFECT QUARTER.

A fine Jersey cow, ten years old, now dry and due to calve in about two weeks, has one teat from which no milk or very little was obtained last year. Cause of losing use of same unknown to me, as have lately come into possession of her, but I suspect a case of milk fever at last calving. That quarter of bag is now developing as perfectly as the other three, from which milk can now be drawn freely. It is impossible, however, to start any milk from that teat. A. B. M.

Buffalo, N. Y.

ANSWER.

Milk fever was not at all likely to be the cause of the blind quarter alluded to. No doubt, garget was. I don't believe the quarter can be restored, if it is the quarter. If it is in the teat, you may be able to draw out the milk with a safe, easy milk tube. I know of no other method. You may have blind quarter and blind teat also. An expert alone is the one to ascertain this. Such an aged cow is not an easy subject when the milk process is in question.

PINK EYE.

We have a disease among the cattle here which some think is pink eye. The eye begins to water and is of a pinkish cast, then a heavy, white scum covers the eyeball and a good many of them burst. Some get well. It affects young calves as well as cows. The stock otherwise seem to be healthy. Would you consider the milk fit for use?

Clearfield, Iowa. G. N. McN.

ANSWER.

I never fancy milk from a cow suffering from any form of disease. Never use such. Pink eye is bosh. You are passing through an enzootic attack of ophthalmia. The causes for this inflammatory condition are many; colds, injuries of any kind, general feverish condition of the system, etc. Your safest plan is to have an expert examine into the cause and remove it. Immediate full dose of physic is surely good and quite safe, and will be likely to do much good. Tincture of arnica and watery extract of opium, equal parts, water, half a part. Squeeze a little of this into the eye when in the film stage of the disease. Hold up the upper lid and then squeeze a little into the lower lid. Do this in a shady place always. Don't forget the physic. Still, you need a good, practical professional expert upon the premises to investigate fully all the symptoms and the environment generally.

SUDDEN DEATH.

One of my patrons had a 200-pound hog die suddenly and without apparent cause. A few days later a calf died in the same way, both bloating after death. He was feeding pasteurized skim milk. He seems to think the milk had something to do with it.

Berlamont, Mich. C. L.

ANSWER.

Might be, and perhaps was, apoplexy. Most animals bloat—in fact, all do—soon after death, especially in warm weather, if not prevented by some antiseptic, etc. I know little about the pasteurized milk. The milk might be at fault and cause the death. How, I am unable to say.

Horse Owners! Use GOMBAULT'S Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING. *Impossible to produce scar or blemish.*

Same price and same quantity as above.

SAFETY HARD RUBBER MILK TUBES with hole in the end, and DILATING PLUGS

(Patent applied for.)

My Hard Rubber Tubes and Hard Rubber Dilating Plugs supplant all kinds of metal tubes. No blood poisoning or bruising. No dropping out of teat by its own weight. Two hard rubber tubes, 2 and 3 inches long, and two plugs $1.50 the four—and also one bistuary and two plugs $1.50 the three. By mail, the whole set $3.00. In writing for medicine, please say if the cow does or does not come in heat—as the medicines are as different as fire and water.

DR. WM. HORNE, Janesville, Wis.

"Engineers' Bargains," our 64-page book, giving net prices on every article an engineer needs, will be sent to all who write for it. Our goods are all of best quality, and our prices are very low. Besides, we ship from either Chicago or Detroit, as may be nearest our customer. Our book will surely interest you; write for it. DETROIT ENGINEER SUPPLY CO., Detroit, Mich.

Patents on Hydraulic Separators.

Cornell University has issued a bulletin, giving a description of the patents issued on gravity separators. The bulletin contains cuts and descriptions of all the dilution or gravity separators thus far patented.

In regard to a patent on the process of diluting milk for separation, the bulletin makes the following statement:

A striking similarity is observable in all these patents. In none of them except Philips' is dilution mentioned in the claim, and there it covers not the dilution itself, but the manner of it. In all of them, however, dilution is mentioned in the description as an essential part of the process. It would seem, therefore, that in patenting some minute or unessential feature of the can, these people have sought to convey to the uniformed, the idea that the whole can, process and all, was subject to the patent. This is further borne out by the attempt in some cases to collect royalty from people using the dilution process in Cooley or other cans. Since some manufacturers have stated that an application has been made for a patent covering the process of diluting milk with water to facilitate the raising of the cream, it may be well to look into the matter of the possibility of such a patent being granted.

In the language of the patent office an invention, in order to receive a patent, must present "novel, useful, and patentable subject matter." Waiving altogether or granting entirely the usefulness and patentability of this process let us look only into its novelty. The process was certainly well known as early as 1890, for in that year it was the subject of investigation and report by at least three Agricultural Experiment Stations in widely separated parts of the country. It has been argued that these reports, since they did not recommend the practice, should not be considered as evidence that the process was "well known and in common use." But one, at least, of the publications cited did strongly recommend the process, and if recommendation necessary to constitute publicity it would be easy to find it in the agricultural and dairy press of that period.

The late Col. F. D. Curtis, to the personal knowledge of the writer, strongly recommended the dilution process at numerous farmers' institutes in the state during the winters of 1889-90 and 1890-91, and frequently also recommend it in the press.

Prof. E. F. Ladd, then of the State Agricultural Experiment Station, at Geneva, now of the North Dakota Agricultural Experiment Station, also recommended it under certain conditions, and it was frequently mentioned by other writers. It is also recommended for use in connection with the Cooley creamer in circular No. 214 of the Vermont Farm Machine Co., page 10. Under date of May 31, 1899, Mr. N. G. Williams, the manager of the company, informs me concerning the above: "These particulars were in April, 1890, and have been published in our circulars ever since. We had recommended it (dilution) before this." The process was then well known over large portions of the country at least nine years ago, but had almost completely disappeared from public view until revived by these boomers of patent cans about two years ago.

CONCLUSIONS.

Several patents have been granted covering unimportant details of the construction of cans in which the dilution of milk with water is recommended to facilitate the separation of the cream.

Anyone desiring to use this process of doubtful utility is perfectly free to do so without let or hindrance from the holder of any patent right whatever.

The Cornell University Agricultural Experiment Station will esteem it a favor to be put in communication with anyone who is demanding a royalty from persons who are diluting their milk in order to facilitate the raising of the cream.

To Check Hog Cholera.

Prof. Henry Says Isolation or Quarantine is the Hope of Farmers.

An East Troy, Wis., correspondent, of the Wisconsin Experiment Station, writes concerning hog cholera and asks if there is any method of inoculation or vaccination which is practical and efficacious, and Prof. Henry offers the following suggestions:

"On more than one occasion notices have appeared in the public press stating that the Department of Agriculture, Washington, had a method of inoculation or vaccination, to prevent hog cholera. In reply to a letter addressed to the department by the writer, we were informed that such statements were premature, though hopeful experiments were in progress. Wisconsin farmers may rest assured that as soon as anything positive is accomplished in this much needed direction, the public will be promptly and fully informed of such help.

"For the present the hope of farmers in staying the dread disease must rest in isolation or quarantine. In all veterinary matters the state of Minnesota is a dozen years ahead of Wisconsin. There they have a powerful board of health which is working vigorously in this matter. As soon as hog cholera breaks out, the premises where it appears, are put under the strictest quarantine according to modern ideas of what is proper. As a result, hog cholera is surely being driven out of the state. The Minnesota state board of health saves its cost to the people many times each year.

"In Wisconsin we have a state veterinarian, who is doing the best he can to check the plague, but he is cramped for means and for assistance. Until our farmers wake up in this matter, affairs will drag along as they are now doing, with enough money lost every year to pay for a dozen state veterinarians."

"If hog cholera breaks out in any locality in Wisconsin, I urge our farmers to write or telegraph immediately to Dr. H. P. Clute, State Veterinarian, Marinette, Wis., urging his immediate presence. Dr. Clute will come to the premises as soon as possible and no doubt place a quarantine thereon. Farmers are urged to carry out the orders of the veterinarian in regard to the quarantine in all particulars.

"The disease is often spread by sympathizing neighbors who come to look over the sick animals and give their opinion as to whether it is hog cholera or not, and to offer some of the many cure-alls which everybody has to recommend. Those visiting the premises carry away the disease on boots and clothing. Wagons passing over the affected districts may carry the disease on the wheels. Rats are also conveyors of the disease germs, as are streams of water. Prevention is better than cure, and no matter how good a preventive we may hope to have, we should at once educate ourselves in the untold value of strict quarantine systems. In Europe, the great cities have now reached a stage where they no longer dread Asiatic cholera. It is not because they found a remedy for Asiatic cholera, but because they have learned how to quarantine against it and prevent its spread.

"The writer of this reply believes that if Wisconsin was to spend a few thousand dollars each year, for a few years, on hog cholera quarantines, the state would soon be rid of the disease, and once free from it, we could, by the same system, carried out relative to stock brought into the state, keep the losses down to an insignificant sum. When once our farmers are thoroughly educated as to the great values of quarantine, the knowledge so gained will be helpful in many ways. Such knowledge would aid in suppressing diphtheria, scarlet fever and other plagues among human beings. We would also be prepared to act quickly and intelligently when new contagious diseases attacked our farm animals."

THE JONES UMBRELLA "ROOF."

A NEW UNION TWILLED SILK "ROOF" $1.00

RE-COVER YOUR OWN UMBRELLA.

The Adjustable "Roof" fits any frame, requires no sewing, and can be put on in a minute. You can re-cover your own umbrella without the slightest trouble or moments delay.

Take the measure (to the fraction of an inch) of your old umbrella; count the number of outside ribs; state if the center rod is steel or wood; send to us with $1.00 and we will mail postpaid, a Union Twilled Silk 25 or 26 inch Adjustable "Roof" (27 or 28 inch, $1.25; 29 or 30 inch, $1.50). Umbrella "Roofs" all sizes and prices from 50 cents to $8.00 each, according to quality. If you are not absolutely satisfied in every particular, send the "roof" back, and we will refund the money *at once*, including stamps you have used for postage. Over a quarter of a million "Roofs" sold.

Booklet, "Umbrella Economy" with simple instructions necessary with your order.

All first-class dealers sell Jones Umbrella "Roofs."

The Jones-Mullen Co., 396-398 Broadway, New York.

THE NEW BOOK Feeds and Feeding

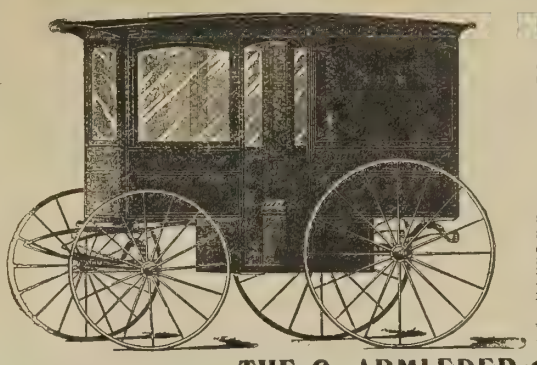
By Prof. W. A. HENRY,

Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.



Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

WE make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue, which fully illustrates and describes this wagon and 10 other styles.

THE O. ARMLEDER CO., Cincinnati, Ohio.

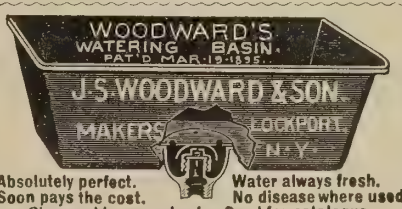
Be Fair with Your Fields

and they will be fair with you..... Listen a moment.



Every time you take a crop off a field you relieve it of just so much fertility. You should do something to restore that fertility. Barn yard manure is the best fertility restorative known if properly handled and properly applied. Even a small amount can be made to go a long way and accomplish great good if finely and evenly spread. This cannot be successfully done by hand—it is work for a perfected machine. The only machine known which accomplishes this is

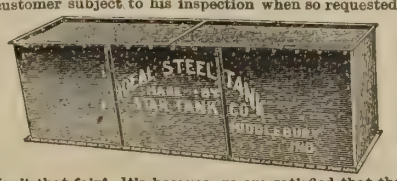
The KEMP MANURE SPREADER.

It will Double and Treble the Value of the Manure Heap.

It spreads all kinds of **fine and coarse manure evenly;** it makes no "skips;" does not dump a great load in one spot, but covers the entire ground evenly. Tears up coarse and lumpy manure and makes it fine. Better than anybody can do it by hand. **Spreads lime, wood ashes, salt, etc.,** equally well. With the drill attachment **it puts the manure direct into the open drill.** Made in three convenient sizes. Ask the opinion of anybody that uses one. **Write for illustrated catalogue.**

Kemp & Burpee Mfg. Co., Box 46, Syracuse, N. Y.

Absolutely perfect. Soon pays the cost. Cheapest because best. Water always fresh. No disease where used. Send for catalogue.



Water in the Stable a Necessity.

It is now regarded as a necessity that stock in the stable should have constant access to water of suitable temperature. The dairyman who today turns out his cows to drink, is as far behind the age as the farmer who cuts his grass with a scythe, or rakes it up with a hand rake. Write for descriptive catalogue of the best known and best System of watering Devices for Cattle in Stables to

SMALLEY MFG. COMPANY, Sole Makers, MANITOWOC, WIS.

MAKE ONLY SWEET ENSILAGE

Ever since the ensilage system has been introduced in this country it has been the ambition and effort of siloists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste,

The best way to Shred Ensilage is with the

St. Albans Ensilage and Fodder Shredder.

It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail free a pamphlet on the subject.

ST. ALBANS FOUNDRY CO., ST. ALBANS, Vt.

DAIN THE BEST, THE CHEAPEST, THE STRONGEST, THE MOST DURABLE STEEL CORN CUTTER.

A PRONOUNCED SUCCESS---THE VERDICT IS UNANIMOUS.

An Entirely New Departure. STRICTLY UP TO DATE.

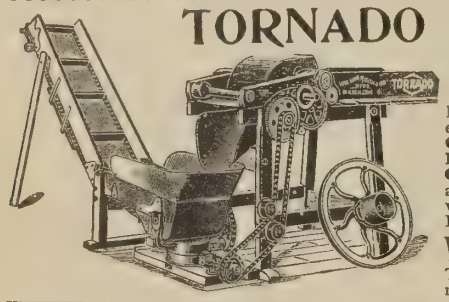
"I think it by far the best corn cutter I ever saw." H. G. WILLIAMS, Shenandoah, Ia.

"Works splendid. A valuable implement; an absolute necessity for every corn grower." N. GIBBS, Mt. Vernon, Mo.

"Find it satisfactory in every way. I would not raise corn without one." J. S. HOCKING, Wheatland, N. D.

"A success and a great labor-saving machine. Every farmer ought to have one." O. E. BROILS, Browning, Mo.

"The best corn cutter I ever saw." A. W. SCARBOROUGH, Elmo, Mo.



"Works perfectly. Can cut from five to seven acres per day." ABRAM GILBERT & SON, Franklin Grove, Ill.

ADJUSTABLE, PRACTICAL, SAFETY SEAT, EASY TO RIDE, SAFETY SHAFT, SAFETY GUARDS, REASONABLE IN PRICE.

It will cut more corn than any device ever invented and at less expense (machines costing $100 to $150 not excepted). For special information, prices, etc., address

"PURIFINE" A BOON TO THE GREAT DAIRY INTERESTS.
A POWERFUL **Disinfectant** That is ODORLESS, NON-POISONOUS. Used in Creameries, Cheese Factories, Dairies and Stables.
IT DOES NOT Create an Oder to Destroy One.

SAN FRANCISCO, Sept. 22d, 1896.
I have used "Purifine" in cleansing milk cans and bottles and find it will remove the bad odor left by old sour milk more effectually than anything I ever tried.
E. A. GREEN, Sec'y,
Millbrae Dairy Company, Mission & 9th.

Applied with large quantity of water, which makes it **cheap and convenient of use.** It is invaluable to the cleanly dairyman or factory operator. Once try, you'll never be without.
SEND $1.00 FOR SAMPLE GALLON by Freight.
This powerful disinfectant creates no odor of its own, but will keep creamery, cheese factory and dairy pure and sweet. TRY IT ONCE.
FITCH CHEMICAL COMPANY, Bay City, Michigan.

$22.40 for 15 cts.
The additional cost of using Diamond Crystal Salt in the making of a ton of butter is 15 cts. Wiggin & Upham, the produce commission merchants of Boston, says: "Tests prove that butter made with
DIAMOND CRYSTAL SALT
is found to be worth a cent a pound more than butter salted with any other salt." It's not can you afford to use Diamond Crystal Salt, but can you afford not to use it? Send for our book "*The Salt that's all Salt.*"
DIAMOND CRYSTAL SALT CO., St. Clair, Mich.

Write It in The Contract.
What Shall I Write?
Just this:—"Please ship to me a SHARPLES TUBULAR SEPARATOR. I will immediately put it into my factory and will give it a fair and careful trial. If I like it in every respect and it does all claimed for it, I will keep and pay for it. If it fails to suit me for any reason, I will notify you to that effect, and on receipt of instructions from you, will reship to you order as you may direct."

We know 'tis a wide open proposition on our part, and invites trouble from the unscrupulous creameryman and the unprincipled separator agents who swarm around every Tubular that is placed, trying by fair or foul means to displace it. But our faith in humanity is large. Out of hundreds of Tubulars placed on such liberal terms, not a dozen creamerymen disposed to listen to the unholy propositions of competitors, or to take an unfair advantage of our liberality, have been found. A few betray our trust for reasons best known to themselves, but we try to steer clear of that kind.

THE SHARPLES TUBULAR SEPARATOR
Has merit that will win. It is a hollow bowl separator. It has no metal bearings except the ball bearing on which it spins. The bowl alone revolves.
It is a clean, rapid, superb skimmer of large capacity. The best creamerymen everywhere are using it or about adopting it.

Do You Know What a Good Tester Is?
It is one that makes little noise; that has small vibration; that runs easily; that will do accurate work.
THE STANDARD BABCOCK TESTER
will last for years. It is built for the creameryman who believes that it pays to have **high grade machinery at a reasonable price.** The Standard Tester has a solid cast iron frame and is supplied with the famous Glass Eye Speed Indicator.
IT USES THE ORDINARY BABCOCK BOTTLE.
Farrington and Woll's new book on Milk Testing with each machine. We are prepared to repair all separators, and have the most experienced men for this work. You will be interested in our free catalogue No. 61.
Address, ELGIN MANUFACTURING CO., ELGIN, ILL.

AT THIS season of the year the preservation of milk demands that it be cooled in some manner.

With the

Champion Milk Cooler

May be Cooled and Aerated in one Process,

The Aeration removes all unpleasant oders from the milk. The cooling reduces the temperature quickly so that the keeping quality of the milk will be much improved.

The **Champion Cooler** can be used with ice, cold well water or running water. There is no other Cooler so convenient and so effectual.

No Dairyman can afford to be without one of these Coolers. The price brings them within the reach of all. Write for booklet, "Milk and its Care," which tells all about them.

Reading notices, 50 cents per line (nonpariel measure) each insertion

THE Iowa Experiment Station has added to its herd the two high-class bulls, cuts of which are given on this page.

After considerable search Prof. Curtiss selected a fine animal of Combination blood, Spree 31698 from the herd of H. C. Taylor, of Orfordville, Wisconsin.

This is an animal whose pedigree stands high on the list of the butter producing families, as well as in dairy form and constitution.

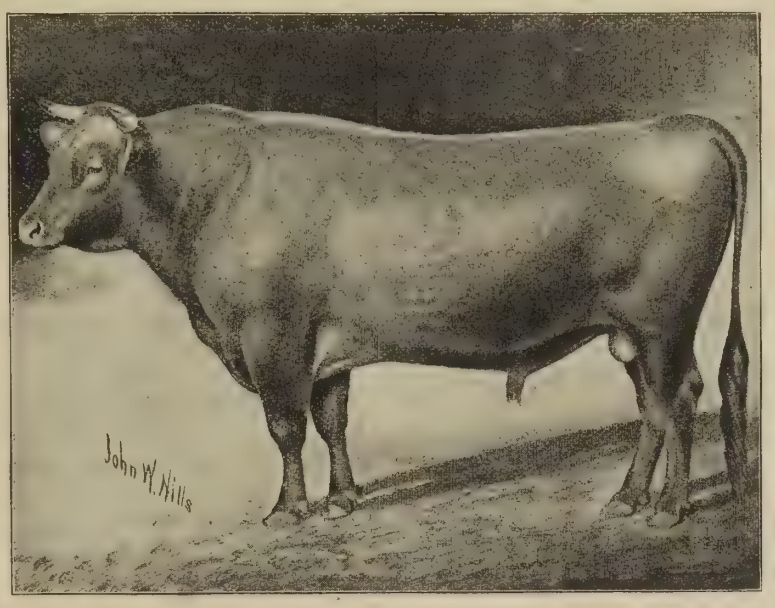
As a worthy companion to the above, the Holstein bull Sir Abbekerk Mechtchilde whose dam has a record of seventy-seven pounds of milk testing 4.4% fat in one day, was also purchased.

The Iowa Agricultural College is to be congratulated on obtaining such fine examples of the two great dairy breeds.

IMPROVE THE COWS.

Ex-President Burchard said, in his address to the Wisconsin Dairymen's Association, last winter, that every farmer ought to sell his hay and grain to a cow just as he would to any other buyer. Practical men do not keep on selling hay and grain to men who do not pay. Why should they not exhibit as good financial sense, when they sell the same food to a cow, and he added:

"I know whereof I speak, that it is just as easy to have a herd of cows that will average more than 275 pounds of butter per cow, or 600 pounds of cheese every 12 months, as it is to have one that will average less than that."



Every farmer, who is trying to keep cows for profit, can start on this road, if he only thinks so. The first step is to get a good dairy sire. We know of hundreds of farmers who have commenced in this way, and in a few years they had a herd of cows that averaged easily a hundred pounds of butter per cow, more than the original herd. If you cannot afford a full grown bull, get a registered calf and raise him. Don't breed from a grade sire, no matter if he does look like a thoroughbred.

SOME DAIRY FAKES.

A few days ago, a correspondent sent us a copy of a so-called produce paper, and with it were three recipes supposed to be given as a premium (?) to the subscribers of the paper.

It would seem that at least one of these receipts is being extensively circulated, as butter made according to the so-called process is beginning to appear in the market. The *National Produce Review*, of Chicago, prints the following:

"Another dealer, who is an extensive buyer of butter, has purchased quite a bit of this stuff, and when asked what he did with it, he said he simply put it through a process and got all the oil out of it, and threw the rest away, and even in this way it is hard to get his five cents a pound out of it. He said that there was not over thirty to forty per cent of butter in it. Others seem to think that it will hold up to fifty per cent of butter. It is very evident there is no money in this stuff, and the sooner the makers stop shipping, the better off they will be, as well as the market."

JERSEY BULL, SPREE, A. J. C. C. 31698.

Property of the IOWA AGRICULTURAL COLLEGE, Ames, Iowa.

This butter is made by the "Holland process," and by the use of "Butter Rennet." What this last compound does is shown by the following selection from the circular:

It commences with the following statement:

"Science has demonstrated the fact that butter is composed of microbes, the development of which add to the quantity as well as the quality and flavor of the butter."

And then continues as follows:

"Take as many pounds of water as you have pounds of butter, then get a package of Richard's Butter Rennet, which costs $2.50 per package. Add three teaspoonfuls of dissolved Butter Rennet to each ten lbs. of water, pour the water into your churn with your butter, and churn it for about two or three minutes, and you will have a perfect combination of the water and butter, by which all the solids contained in the butter are developed, and after working and salting as you do ordinary butter, you will have one-half more butter than you started with."

We don't know what the composition of the "Butter Rennet" is, nor is it necessary to know, although we could make a good guess as to its composition. But we do know that butter made according to the above method is a fraud as to its flavor, keeping qualities, composition, and market value; and the dairyman who allows himself to be persuaded into manufacturing such stuff will not only lose his market for butter, but also render himself liable to prosecution for food adulteration. No market or customer is going to purchase butter with forty to fifty per cent of water content.

The following selection from the circular will prove interesting; especially the statement as to the cost of the article:

"The heating of the butter, and the adding of the warm water and Butter Rennet, matures and developes the microbes, just on the principle that the incubator developes the chicken in the egg, and this development not only adds to the weight of the butter, but also greatly improves the quality. It will only take a few trials to become perfectly familiar with this method, and it will be worth thousands of dollars to any person dealing in butter. Richard's Butter Rennet is worth $2.50 a box, and it is claimed each box used as directed will make 500 pounds of actual increase in weight."

Along with the above is a process for the preservation of eggs, calling for the use of "hyper-samphire" at $2.50 per box of four ounces. It is a good name, but hardly worth the price.

Eggs can be perfectly preserved by the use of lime and salt or silicate of soda. There is no chemical used for the preservation of eggs that is worth over ten cents per pound. It may be seen, therefore, that $10 per pound charged for "hyper-samphire" comes nearer stealing than profit.

Compound extract of salyx at $10 per pound is also advertised for preserving fruit. This is salicylic acid, which can be bought wholesale for forty cents per pound.

It is said that there is a new crop of fools born every year. However this may be, we see no reason for the readers of the DAIRYMAN being included in the above list for want of a little warning.

HOLSTEIN BULL, SIR ABBEKERK MECHTCHILDE, H. F. H. B. 20124.

Property of the Iowa Agricultural College, Ames, Iowa.

ANOTHER ARGUMENT FOR THE TEN CENT TAX ON COLORED OLEOMARGARINE.

The Massachusetts dairy bureau recently had three oleomargarine cases in Brockton, two for serving it in restaurants and one against a dealer. The restaurant cases were tried first, and the proprietors swore positively that they supposed they were serving butter. The substance, which they were serving, was bought as butter and they had every reason to suppose that it was butter. On being questioned as to the party of whom they purchased, the reply was "Mr. Chase," the same party whom the next case was against. When that was reached, after the regular evidence of the bureau had been put in, Mr. Whitaker called the defendants in the two previous cases as witnesses against Mr. Chase. It is needless to say that convictions were secured in all of these cases.

Here you have it—two honest retailers victimized by the man who is working in the interests (?) of the poor, laboring man, by selling as butter and at the price of butter a compound of hog fat, gut tallow and cotton-seed oil, colored to resemble butter. If he, or the millionaire manufacturers whom he represents, had been compelled to pay a revenue tax of ten cents a pound on this vile compound, his zeal for selling it in this fraudulent way would have been proportionally decreased, because the profits would have been reduced, and the retailers would have escaped conviction and fine and the final consumer's stomach been relieved of the extra labor of digesting the noxious stuff.

New York Silo Experience.

ED. HOARD'S DAIRYMAN:—I have a silo which has been filled seven times. It is octagon in shape, and the inside has never been painted with anything. The lining is two thicknesses of six-inch, matched lumber with tar paper between. It seems to be tight and all right, but for two or three years the ensilage has molded considerably, increasing each year. The mold is more often found opposite girts, but is found, sometimes, in other places, and sometimes patches will be found that will not run to the side of the silo. Last year the corn was in prime condition; the year before it was rather dry.

It looks to me as though the moldy spots might be caused, somewhat, by the moldy patches on the boards infecting the ensilage, and growing out into it. When the silo was new, there would be small patches of mold on the boards, and they seem to increase from year to year. They began along the girts first.

The wall under the silo comes above the bottom about six inches, and extends inside about the same, and for two years the ensilage has rotted for a foot or more next to it, with no good reason as I can see.

What is the best thing I can do to prevent the ensilage spoiling? Would whitewash kill the germs of mold so that it would not infect the ensilage, or would some kind of coal tar paint be better? G. W. SHAW.

St. Lawrence Co., N. Y.

Whitewash would unquestionably answer the one purpose of preventing the spread of the infection, but for all purposes, a coating of coal tar would be better.

A spring scale, a Babcock test and a good churn are the three things needful for an accurate testing of the milk and butter capacity of a cow. Other things may facilitate the work of butter making, but these three are essential to knowing the quantity of milk, the quality of milk and its butter making capacity.—*Jersey Bulletin.*

We had supposed that the laws of the Medes and Persians were no more change less than the rooted objection of the *Jersey Bulletin* to the Babcock test. It has taken some nine years to make the change and during that time the *Bulletin* has passed through the various stages of negation and objection, until now we are told that the test is essential. Verily, the way has been long and tedious, but none the less we welcome the conversion of our contemporary.

STUPID AS WELL AS STALE.

The *Jersey Bulletin* of the 2nd instant, in one of its periodical and abortive attempts to be smart, says:

"We have the escutcheon from France, the pelvic arch from Ft. Atkinson, and curly hair on the shanks from some other "seaport" —all to tell the milking qualities of a cow—but the latest comes from Sweden."

And then it proceeds to quote the some-years-old report about determining the quality of the mature cow from an examination of the "palps" on the inside of the cheeks near the corner of the mouth.

"The pelvic arch from Ft. Atkinson" is as witty as anything that has appeared in the *Bulletin* for many months. It is almost as innocently cute as the city maiden's inquiry for the cow that gave the buttermilk.

THE FODDER CROP.

There is much wisdom given in the article, "How Best to Utilize Corn Fodder," on page 514 of this issue. There can be no doubt that there will be a scarcity of good hay next winter, in many states, owing to the severity of the past winter; and very much of the hay gathered is of inferior quality, for milk food, because it is too ripe. Besides, the wet weather has injured much of the hay in many localities.

Every farmer will need to keep a provident eye out this season to save all good fodder he can, and in the best possible condition.

Good, bright corn fodder (by this we mean corn grown for fodder) well cured is the equal, ton for ton, in our experience, with timothy hay for milk making purposes.

Good corn stalks come next to it. If pains are taken to cut the corn a little early, and thus let the ear ripen in the stook, the fodder will be very much better.

Then it should be well cured and bound, and if run through a cutter, sprinkled with water and allowed to stand in a heap on the floor until it heats and softens, it will prove a splendid milk food.

Those farmers, who have laid their fodder cutters aside for two or three years past, will need to get them out again to cut up the corn stalks. It will pay every time to put stalks in the best possible condition for the cow to eat. The labor required for this is cheaper in a hired man than when the cow is forced to do it.

Fortunate is the farmer this year, who has a good silo, into which he can store an abundance of rich, succulent food for his cows next fall and winter. In view of the great profit the silo brings, it is amazing that so many farmers are so hard to convince concerning it.

JUDGING DAIRY CATTLE.

HOARD'S DAIRYMAN is always pleased when it can quote approvingly from its contemporaries. In view of some radical differences of opinion with the *Breeder's Gazette* a few months ago, especially in regard to the awarding of premiums to animals in the dairy classes at the fairs, and the subsequent discussions as to the dairy form and its indications, we are particularly gratified in being able to reproduce the following article from its issue of the 26th ultimo:

The judging of dairy cattle is attended with the gravest perplexities. It is comparatively simple and easy to allot positions among beef cattle. Form, quality, and bloom are the points on which to hang a decision. If the model beef form is approximated, if breed type is present, if quality is marked and bloom apparent, the judge confidently approaches a decision. That the form is adapted to function is proved by the condition of the animal; that is, the outward manifestations fix the animal's value for beef purposes. However difficult it may be to balance the contending claims of animals of this class the judge is much more certain of his ground than when attempting to estimate the respective merits of dairy animals. Of course, we have made a close study of form as related to function; we have deduced therefrom a distinct type which we call dairy form. We have even reduced this type to a scale of measurements in the hope of getting aid from mathematics—but what man among us is there who will venture to say how much milk or butter a cow will make simply by looking at her? What man is there who will pretend accurately to estimate performance by form? Can you tell how far a frog will jump by looking at him? Can you estimate the speed and stamina of a horse in the show ring?

With all our standards, in very truth we work much in the dark when we come to estimate the ability to render a certain performance, such as milk-giving or running or trotting, merely by an examination of the form of the animal. We can but guess at best. Of course there are those cocksure individuals to whom a much vaster wisdom (in their own estimation) has been revealed than to the common herd, and some of them have no difficulty in persuading themselves that they possess well-nigh infallible powers of discernment; but the man who milks and uses the tester knows that he cannot know, without the testimony of the scales and the test-tube.

But our lack of positive knowledge, derived from a physical examination of a dairy cow, is no reason why the exhibition of such cattle should be abandoned, nor does the fact that the decisions of the judges, frequently, vary widely from the evidence of the churn, warrant us in abandoning show-ring judging and resorting solely to tests. Type, as related to food consumption, is pretty well defined, and our show-yard awards have been valuable as tending to weed out types that are unprofitable at the feed trough, and produce uniformity of physical charactistics; moreover, enough is known of form as related to function to remove our show-yard adjudications from the plane of a farce. But every possible aid in arriving at a correct decision in a ring of milk cows should be invoked by the judge. One of the chief aids in this direction is an examination of the cows with empty udders. This of course involves milking the cows in the ring, as they should first be inspected with full udders—not painfully tense and hard, but in a state of full distension. It is remarkable therefore that the Council of the Royal Agricultural Society should have adopted the following rule: "That no animal in any cow class be milked in connection with the judging."

The Rev. A. Baillie-Hamilton, judge of Jerseys at the recent Royal Show, ordered the cows milked and was taken to task for it. He then directed the men to cease milking and milked the cattle himself. Afterward he suggested to the Council that they allow the judges of dairy breeds the privilege of having cows milked in the ring. To this request for bread the Council gave the stone of the resolution quoted. We are wholly at a loss to account for such action, especially as it appears that Mr. Baillie-Hamilton was the spokesman of the exhibitors of dairy cattle, in proffering this request. We regret that the published accounts of this incident do not indicate in any way the ground on which the Council rested its denial of this most reasonable and necessary request. From our point of view its refusal to permit a judge such opportunity for reaching a decision is nothing less than amazing. Certain it is that fair managers on this side are always ready to aid their judges in this way, and the practice of milking out the leading candidates for honors is rapidly growing. It should be the rule rather than the exception.

It is barely possible, though hardly probable, that the *Gazette* has misinterpreted the meaning of the rule adopted by the Council of the Royal Agricultural Society. If the intent of the rule is simply to exclude from consideration by the judges, the amount of milk that may be obtained, whether unnaturally increased by delayed milking, or decreased by fright or otherwise, it seems to us a move in the right direction. If a milk test for two or three days may be misleading, how much more unreliable must be the result of a single milking, even under normal conditions?

On the other hand, if the operation of the rule, whether so intended or not, shall be to give greater importance to the size of the udder and thus encourage exhibitors to omit milking at regular hours and intervals, the *Gazette's* criticism is, if anything, only too mild.

To Make Butter or Sell Milk.

ED. HOARD'S DAIRYMAN:—Which would pay better, to make butter at an average price of 18c net per pound the year round, or to sell milk at an average price of $1 per hundred pounds, on a basis of four per cent butter fat, with two cents per hundred pounds of milk added for each one-tenth above four per cent? Will selling milk at above price pay better than mixed farming at present prices for grain and stock? W. C.

Cedarville, O.

There are several considerations, not mentioned above, which enter into the problem,—such as, does the price for butter exclude the cost of making, or must there be a further one cent or two cents deducted from the net price given? Eighteen cents for the year is not a very strong price and one might reasonably expect to do better, especially with an established trade. Then there is the skim milk and buttermilk. Under certain conditions, these can be made to pay handsomely. Then there is the expense of delivering the milk, if it is sold.

One hundred pounds of four per cent milk will yield from 4½ to 4⅔ pounds of butter, and 95 pounds skim milk and buttermilk. At 18 cents per pound the butter will return from 80 to 85 cents, and the buttermilk and skim milk, judiciously fed to chickens, pigs or calves, would easily bring the total to one dollar.

We don't know of any market that will pay as much for farm grown crops (or the feeds which may be had in exchange for them) as a good dairy cow, even at present low prices for dairy products. We seldom treat the cow fairly in the matter of debits and credits. In the first place, we charge her full retail prices for every pound of hay and grain she eats, with no allowance for the saving in hauling, and after that refuse her credit for the various by-products,—manure, calf, skim milk, etc. Then we ask where is the profit? When the cow pays the farmer for his hay and grain, as much as he could realize for it in market, she makes him a better profit for the extra capital and labor employed that can be realized in any other line of legitimate business. We are both amused and indignant sometimes, at the "figures" submitted in the attempt to prove that "dairying" is not profitable. Not long since we had a letter from a man who had been in active business in a city for some years, that brought him a very satisfactory income, but tiring somewhat of the city as a place of residence for his family he bought a farm, an hour's ride away, spent some $15,000 or more for improvements to house and barns, bought some thirty or forty cows, and put expensive help in charge, and was disappointed to learn that the income from the cows did not pay running expenses, keep up the establishment, support his family and their hosts of visitors and in addition return him good interest on his investment.

Cow Comfort in Summer.

Heat, Flies and Fodder.

ED. HOARD'S DAIRYMAN:—July and August are trying months for the dairymen. Anyone, with a little snap and get up, can make his cows comfortable in winter, but to make them comfortable during the hot months and fly time is much more difficult. The pastures are brown and hard, the brook has stopped flowing and the water is stagnant.

The flies are a terrible torment the whole day long. There is no shade in the pasture lot and the hot sun beats down on the cows to make the heat almost unbearable. There is no provision in the stable for ventilation, and if the cows are kept in the stable during the day, to keep them out of the hot sun and the flies, they must be in a dungeon and matters are not much improved.

If we have a properly constructed, ventilated stable we can not do better than keep them in during the day, and pasture at night. Unless we make every effort possible to keep up the flow of milk there is sure to be a shrinkage, and no matter how good you feed later you will not re-establish the former normal flow, and the loss is much more than a little attention and feed at the proper time would have cost. I speak from sorrowful experience.

It pays well to make an effort to reduce the fly torment. I find by spraying my cows and stable every morning and evening with coal oil I can materially reduce the flies. I use a little hand vaporizer that costs fifty cents.

I have a fine shady pasture ground with nice spring water and before I turn out the cows I find it pays to apply Shoo Fly. Good pure water is a very large item and in the hot weather the cow must have plenty of it at all times. It pays well to see about this.

It also pays well to have a supplemental feed of some kind to feed morning and evening in the stable. I have and prefer silage, but if you have no silo you still can have an acre or two of some medium early sweet corn (Crosby's Early is splendid) to come in

just when all early crops are mature and cut, and the field corn is not yet fit.

Cow peas and kafir corn, sowed as early as the weather will permit, also made me a splendid feed for just this trying time. Don't be afraid it will not pay to feed grain, even though the price of butter be low; it will help to make more later when the price is up again. In short, if we would have our dairy profitable, we must keep our cows well fed and comfortable during the hot months.

Adams Co., Pa. L. W. LIGHTY.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

PARTITION AND DRAIN IN A SILO.

Our silo, built five years since, has not been very satisfactory and we wish to make some changes that will make it better. In size, it is 36 feet long, 18 feet wide and 20 feet deep. This leaves most too large a feeding surface to feed from top. We have thought of putting a partition through the middle. This partition of two inch plank with a couple of rods in partition to keep it from spreading. This would practically make two silos. We have had more or less trouble with rats and mice working in at the bottom. In cementing ground is it necessary to have a drain? Can you suggest any other way of fixing this building that would make it better than our plan? Do you think that after ensilage was fed out of one side partition would be apt to spring?

Hampton, Ia. W. B. BARNEY & CO.

There would be no objection to putting in the partition in the manner you suggest, but it would be better if of double thickness with paper between to make it air tight. If the silo is filled so that the pressure is the same on all sides of the partition while the silage is settling, there will be no springing of the partition, and as there is little pressure on the sides of the silo after the contents have thoroughly settled, the partition will not spring. It should, however, be air tight to prevent the silage from spoiling next to the partition, and the corners should be filled out.

No drain is necessary when the bottom of the silo is cemented. It should be remembered that the tighter the silo, the better will the silage keep, and also that if the corn is siloed at the right condition there will be no liquid formed from the crushing of the corn, and consequently no need of a drain in the silo.

CHEESE STORING TEMPERATURES.

At what temperature should cheese be kept to obtain the best results? Should cheese that is intended to be taken from storage during the warm weather be kept at the same temperature as that which is intended to be taken from cold storage in the fall and winter months? Should cheese in storage be turned at regular intervals, and if so, how often? H. L. S. M. Co.

Salina, Kan.

To make assurance doubly sure in this case, the inquiry was referred to a friend in Sheboygan County, where large quantities of cheese are gathered annually, both for present and delayed shipment, and he writes in reply as follows:

"There is some diversity of opinion. If cheese are pretty well cured, I think 40° about right, whether cheese are taken out before winter or not. It would be a good plan to turn the cheese, but I do not know of any storage company that does this. In fact, it would be almost impossible to do this in the majority of cases, as the cheese are piled in so close."

COOLING MILK.

I want to run water through my ice house to cool milk down to 55° in summer time.

If you can give me any advice as to the best and most economical arrangements of the pipes, I shall be deeply grateful.

Somers, N. Y. T. C.

We do not know of any economical method for using cold water and piping, for cooling milk in bulk. The only economical and practical way for using water for this purpose is to have a stream of cold water running into and out of a covered tank, and set the cans of milk in the cold water. Of course, this does not mean that it is not practical to cool milk by running it in a thin film, over pipes, through which cold water is run. This is an economical and simple method, but we do not understand that our correspondent wishes to use this last method.

WHIPPING CREAM.

I understand that there is a method of thickening cream which is raised in a creamery, so that it will whip readily.

I write to you in hopes that you can give me the necessary information through the columns of your valuable paper.

I am at present selling cream, which is rich and good color, first-class in all respects, except the difficulty of whipping.

Groton, Conn. E. S. T.

Whipping cream depends on its richness and the temperature at which the whipping is done. For this purpose cream should contain over twenty per cent of fat, and as high as forty per cent is used. See that your cream is cooled to below 60° F., and you will not have any trouble.

The method you refer to is the addition of sucrate of lime to pasteurized cream, for the purpose of thickening it. You can obtain a description of the method by writing to the Wisconsin Experiment Station, Madison, for their bulletin on the method.

CATCH CROP FOR COLORADO.

What can I sow on a sod patch of eight acres, at this time of the year, and in this part of the country, with plenty of water to irrigate, up to the middle of August? F. A.

Mouldair, Colo.

We are hardly competent to advise in a case like this. We incline to the opinion that we would try some kind of root crop, unless local experience should pronounce to the contrary. In that event, possibly nothing would be more certain to repay for the labor expended than common millet, or, what is practically the same, Hungarian grass.

DOORS IN THE SILO.

You will find enclosed a check for two dollars, payment for copy of "Feeds and Feeding," by Prof. W. A. Henry. Does this book give full instructions as to the construction of silos. I judge by reading your paper that the ensilage is taken out of the silo by a series of doors, which seems to me to be an inconvenient way of getting it out. Would the ensilage spoil if a door was made air tight on a level with the floor and the ensilage taken out of this door only. If Prof. Henry's book does not give full information on the construction of silos, I would like the name of some work that does.

Prescott, Arizona. J. W. D.

Ensilage does not keep well after the silo is opened, and air is allowed access to the warm, wet ensilage. Consequently, taking the silage out at the bottom would allow the air to permeate the mass and cause molding.

Woll's Book of the Silo is up to date on everything connected with the silo. It can be obtained of this office for one dollar, postpaid.

PREPARING A COW FOR TEST.

Have a cow that will calve in one month. She is in good pasture at present; looks well, wish to enter her in test in October, what treatment should I give her? Have clover hay, bran, ground wheat, oats and flax seed.

Liberty, Idaho. C. H. B.

The above inquiry bears date of July 27th We may say, therefore, that the cow will be fresh about Sept. 1st, or, say, six weeks before she is tested. Presuming that she will come through calving in good condition, let her be fed sparingly for about five days and then increase feed gradually from week to week, being careful not to over feed at any time, and yet keep her well up to her limit of digestion. The principal reliance must be in the oats, bran and clover hay. Give flax seed quite sparingly, barely enough to keep the bowels in first-class condition.

About the 10th day after calving, she will probably be eating about twenty pounds clover hay, four pounds bran, and four pounds oats. The third week should find the allowance of grain increased to ten pounds, preserving the same proportions. From this time on, the increase should consist mainly of oats, and the allowance of flax seed be about to its limit of, say, one pound per day. Let there be gentle exercise daily, if possible, and a heaping teaspoonful of salt twice a day.

ENAMEL FOR WET WALLS.

Can you recommend us any kind of "enamel" paint, or whatever called, which applied to brick walls inside, will be hard as Dutch tiles, impenetrable to mould, and thus not liable to show black spots in room with damp, warm and changeable atmosphere? J. M.

Washington, D. C.

We much doubt the possibility of our correspondent's finding such an enamel as he asks for, although it would depend partly on the source of the moisture in the brick walls.

If it is from the outside, a paint of silicate of soda would fill up the pores of the bricks and prevent water from entering, or, if color is no object, a coating of asphaltum dissolved in gasoline might serve the same purpose.

If the moisture comes from the steam in the room condensing on the cold brick walls, nothing but improving the ventilation or another lining to the room will prevent the accumulation of moisture on the walls.

PROCESS BUTTER.

Will you please tell me what is "process butter", how is it made, and what is done with it? I see your journal, last week, speaks again of boiling process butter.

West Liberty, Iowa. H. H. H.

"Process butter" or "boiled butter" is a poor quality of butter which has been melted to separate the casein and water, and then the melted fat put through a process of washing, and rechurning with milk, by which a fair imitation of new, fresh butter is made. It is only an imitation at best, as it rapidly goes off in flavor unless heavily dosed with antiseptics; another is that, also like oleo, much of it was filthy to the last degree, and no amount of boiling or washing can make such stuff appetizing. People will forego the use of butter unless they can be reasonably certain that what is offered to them is clean and wholesome, and always has been. One great objection is that, like oleo, it is sold for what it is not, viz., fine creamery butter.

CUT OR SHREDDED SILAGE.

We have a silo on our farm and would like to know the comparative merits of cut corn ensilage and shredded ensilage. Which is the best for the silo? You may have had the same question up before, but I am a new reader of the DAIRYMAN. E. S. P.

Ripon, Wis.

We have never tried the shredded silage. Those who have, speak very highly of it, and some seem to think it decidedly superior. We incline to the opinion that there may be some basis for this preference where the corn is very large and a little overmature, as it sometimes happens with such that some of the larger pieces from the bottom of the stalks is not eaten. However, we have never been able to convince ourselves that it would pay to discard the cutter and put a shredder in its place.

A COLORADO FEEDING INQUIRY.

Would you kindly advise me how to feed my milk cows in order to get the best results, with feed at the following prices: Alfalfa hay, $6 per ton; corn chops, $16 per ton; bran, $16 per ton; gluten feed, $22 per ton. Please give me two formulas, one with and one without the gluten feed. We are milking thirty cows, nearly all are graded Holstein.

Montclair, Col. F. A.

First of all, buy a feed cutter and power to operate it, for the purpose of "chaffing" a part of that alfalfa hay to mix with the "corn chop." The daily allowance for each cow graduated to her capacity for digestion, assimilation and converting the feed into milk, should be from twenty to thirty pounds of hay and six to ten pounds of the corn chop. We should aim to feed approximately half of this hay "chaffed" and mixed with the grain, and would try chaffing it twelve to thirty-six hours before feeding, adding enough water to the mass to cause it to heat and soften. We cannot say how long this heating mass would keep without injury. This will vary somewhat with the weather and surroundings, and can only be determined by experience.

In the absence of arrangements for chaffing some of the hay, bran must be mixed with the corn chop to "extend" it, so that it can be better digested. Use equal parts by weight.

Gluten feed is not adapted for use with alfalfa hay.

THE VALUE OF MANURE.

We presume you have articles contributed to your paper from time to time, by agriculturists, as to the good that manure has done for their lands. We desire to get as much information as possible, in the way of statistics, on this point; how much more yield per acre there has been of different crops, where manure was used as a fertilizer, above the yield where it was not used.

If you could give us any advice in this matter, or tell us where to seek for same, we should esteem it a favor.

Indiana. L. R. & SON.

The best authority on manures that has come under our observations is The Fertility of the Land, by Professor I. P. Roberts, of Cornell University, Director of the College of Agriculture. It is a cloth bound book of 415 pages, published by the McMillan Company, of New York, and sells at $1.25, and may be had at that price from this office, postage prepaid.

"Statistics" in regard to the benefits resulting from the use of fertilizers of any kind, are liable to be misleading, and we have not been in the habit of gathering or preserving them. Common observation suffices to teach that continuous cropping of land, without making any return, results in an impoverishment of the available plant food in the soil. It is the province of manure not only to reimburse the soil in part with the elements thus removed, but also to set forces at work to disintegrate and render available the general reserve of latent potash and phosphoric acid, with which nature has so richly endowed, practically every part of the earth.

AN EIGHT-YEAR-OLD BULL.

A Florida reader had the misfortune, a few weeks' since, to have a fine, young, Ohio-bred Jersey bull killed by lightning. He was intending him for use on his herd the coming winter, and not feeling able to bear the expense of getting a grown animal from the north, asks whether it will be safe to depend upon his old bull, now past eight years old. So far as mere age is concerned, it may be said that while many bulls have not passed their prime at eight years of age, yet it is also true that from over use and neglect, others are practically worthless at that age. If the old bull has been fairly satisfactory the past year, we should not consider it imprudent to keep him another season.

If some of the dairymen in the south, who have first-class Jerseys, Guernseys or Holsteins, would spend a few dollars during the year for a small card in HOARD'S DAIRYMAN, we feel very confident they would receive a good many inquiries from our southern readers for that class of stock.

THE NEW YORK MERCANTILE EXCHANGE FOR THE TEN CENT TAX.

At a recent meeting of the New York Mercantile Exchange, the subject of the ten cent tax came up for consideration. Mr. W. K. Boardman, of Iowa, Vice-President of the National Dairy Union, addressed the Exchange, and presented in a terse way the argument in favor of the effort the National Union is putting forth to secure the passage through Congress of the law taxing colored oleomargarine ten cents a pound. Mr. Boardman said, in part:

"This is a commercial matter, and we ask the commercial centers, as well as the farmers and butter makers, to support the movement.

Over 10,000 farmers have contributed to the fund being raised by the National Dairy Union, which has already reached $8,000. The proposed tax has been indorsed by the National Butter Makers' Association, the Elgin Board of Trade, the Boston Chamber of Commerce and by different dairy associations throughout the country."

After Mr. Boardman's remarks, the following resolution was unanimously adopted:

WHEREAS, Despite the existence of laws in thirty-three leading States forbidding the manufacture and sale of oleomargarine colored in semblance of butter, the product of this almost totally outlawed article has almost doubled in this country the past year, and conditions at present are very menacing to the future of pure butter and dairying; and

WHEREAS, The National Dairy Union, an organization whose membership comprises some 10,000 dairy farmers, and whose officers are well known to us by reputation as workers in the interest of the butter trade, is preparing to prosecute a vigorous campaign in Congress at its next regular session for the purpose of securing an increase in the tax on all oleomargarine colored in semblance of butter, and prohibited by the laws of thirty-three leading States, therefore, be it

Resolved, That the Mercantile Exchange of the city of New York, representing the distributers of butter of this market, do hereby heartily indorse the objects of the National Dairy Union in this movement and recommend to the Representatives in Congress from this state that they use every honorable means to secure an increase in the internal revenue tax from two to ten cents per pound on all oleomargarine manufactured in semblance of any shade of yellow butter.

The above action is convincing proof of what the men who handle butter in New York City think of the objects the National Dairy Union is trying to accomplish.

It is also proof positive of what these men think of the course pursued by the New York Department of Agriculture, the *Country Gentleman*, and all others who are trying to pull down and destroy all organized effort against the greatest fraud of the age. No more triumphant answer to the slanders of the *Country Gentleman* and the *Dairy World* against the officers of the National Dairy Union could be given.

AN OPINION FROM A STRONG MAN.

In the July number of the *Munsey* Magazine will be found two articles on "Modern Industrial Combinations" from the late Governor Flower and Senator Chauncey M. Depew, of New York. That of Governor Flower contains two allusions to the farmer, which are of interest, and which we copy as follows:

"At my own little farm in Jefferson county, I raise ducks. There is a season when the market is glutted, when it is not possible to get their market value. If I had on my farm the facility for cold storage, I could save those ducks, as is done by dealers in the city, until such a time as they were worth a fair price. The dairy farmer will learn to use cold storage in time. He will enter into competition with his neighbors to establish a primitive cold storage plant, and save his product until he can sell it at a profit. If the grape farmer, for example, would put his crops in cold storage, at a time when he is selling them at a half a cent a pound—that is, at a loss—he could get five cents a pound for them later in the year".

Again he says:

"I often hear from the farmers of this state, that they feel they are impoverished by reason of the trusts. The trouble with the farmer of the east is, that he does not realize the new conditions which grew out of the opening of the west, by the extension of great railroad systems. The farming land of the east has fallen in value, but it has merely sought the level of the farming land of the west.

The eastern farmer keeps right on trying to compete with the western farmer in the growing of grain. He can not do it, and the sooner he learns that the better. If he will diversify his crops, and cultivate the home market, he will become prosperous again.

The young people on a farm now, go to the cities because they cannot make a living in the country. If the farmer would only learn to make small cheese, instead of great big ones, and to put them up in attractive packages; to put his butter into attractive shapes, so that it would command a market in the near-by towns, he would get more for his product, and find a nearer market for it."

What Gov. Flower says is of interest, because it comes from a man who was a strong, deep thinker on all lines of industrial development. But his statement is superficial. It does not go to the root of the evil. Eastern farms have declined in value, and the farms of the great Middle west have increased in value, not because of an effort in values to establish an equilibrium, but because of the fact that the farmer himself, in the east, has declined in spirit, pride, enterprise and a true understanding of his true situation. The American born farmer, east and west, has turned his back on his business at too great an extent. In the west the well trained farm peasantry of Europe have taken his place. They have a farm pride and ambition. Consequently, the prices of land go up where they are. In the east, there has been an exodus of farmers to the towns and cities, and no appreciable importation of better farmers to take their places. Because of a lack of farm pride and ambition, they have allowed their lands to depreciate in fertility, as well as in value. It requires real farm education and ambition to handle land under such conditions.

The governments of Europe educate the children of the farmers in the elements of agriculture, in the primary and common schools. As a consequence, they come here fitted and trained to be farmers. Let them take hold of the depleted and depreciated farms of the east, and a change for the better in value and fertility will soon be seen.

There is a hint in all this, for farmers of this country to consider. They should commence at once to demand that their children receive some education in the science of agriculture, as they do in the science of arithmetic in the common schools. This done, and we will soon see a new order of farmers come into possession of the agriculture of the country.

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By PROF. H. L. RUSSELL.]

Second Series, No. XXII.

BACTERIA IN THE SOIL.—THE EARTH ALIVE.

Until recently, it has been customary to look upon the soil as an inert mass, made up of lifeless molecules of inorganic and organic matter. In the light of this notion, the ground is considered a great storehouse of fertility, which is drawn upon from year to year, to satisfy the needs of growing crops. In these latter days, this old idea has given way to a more modern conception, one that is more in harmony with the rest of the processes, that are going on in nature. No longer is the soil regarded as dead, as made up of inert particles that are in a stable state. A closer examination shows it to be teeming with myriads of organisms that are engaged in working over particle after particle, extracting from the same, sufficient nutriment for their own sustenance, and casting off the remainder to be acted on by still other organisms. So the soil, instead of being a dead and inanimate clod, is a beehive of industry.

To understand it aright, to know how to get the most from it, it is necessary to know some of these processes that are going on beneath the surface. In a great many of these, bacteria flourish, and it is our purpose here to consider some of the more important of these, as related to farm conditions.

While it is recognized that the earth is alive with various kinds of micro-organisms, still it must be said that these germs are not universally and uniformly distributed throughout the whole soil. In fact, they, like all of the higher forms of plants and animals, live in close proximity to the surface of the ground.

DISTRIBUTION OF BACTERIA IN THE SOIL.

In the upper layer of the ground, they exist in myriads. In the soil or dust of the street they are particularly abundant, but in all fields, cultivated or not, they are present in immense numbers. The organic matter that accumulates on, or near, the surface of the ground, furnishes abundant food for them. Moisture and a proper temperature are also present, so that the conditions are such as to encourage luxuriant germ growth. While myriads of microbes are to be found in these upper layers, the deeper strata are relatively free from them. Even at the comparatively shallow depth of a few feet (8 to 12) the soil masses are practically sterile, unless cracks and rifts exist, through which bacteria may find their way below.

This surprising diminution in numbers is occasioned as a result of several factors. In the first place, a great many of the bacteria of the upper soil layers are filtered out as the rain percolates downward. Then again, when you pass from the soil proper, to the sub-soil, the amount of organic matter, on which these organisms feed, is greatly diminished. This, one can readily see by the change in color and texture of the soil and subsoil. Lower temperature, diminished oxygen supply, also aid in reducing the development of this type of life. The result is, therefore, that while the surface and the superficial two to four feet are very rich in bacteria, possessing often hundreds of millions in every gram of soil; this number falls greatly as you increase the depth, until at even a comparatively shallow stratum, no life exists in a developing state.

The practical significance of this to human activities is very considerable. The sterility of these deeper layers is what makes the quality of well waters as good as it is. That immense subterranean reservoir of water, known as the ground water supply, is thus rendered practically free from all microbes. If care were taken in sinking wells into the water bearing stratum to have everything sterile, our drinkiug water supply would be practically free from all organisms, but in the piping that communicates with the outside, they find lodgment and conditions that permit of growth.

As the bacterial activity of the soil is confined to the upper soil layers, so are the changes that affect the fertility of the soil. The processes of nitrification, by which the plant is supplied with a store of nitrogen in an available form, cannot go on at the depth of more than a few feet. Lay bare the soil to a point where the organic matter is not present, and you destroy in large part the ability to secure abundant crops.

IMPORTANCE OF BACTERIA IN SOIL PROCESSES.

The importance of bacteria in this universe of ours is nowhere more apparent than when we consider some of the soil processes that are continuously in operation on the surface, and in the upper layers, they are always at work, tearing down organic matter into its elements or simple combinations, and so restoring to the soil those substances that go to make another crop of green plants thrive and grow. In this process, not only are they engaged in that most necessary process, by which the soil is made to yield continuously, without being exhausted in fertility, but they also perform a function that is very necessary to the comfort of mankind. In this removal process, they fill the lowly office of scavengers, rendering the dead, effete matter of a world into harmless and innocuous substances.

Imagine the condition that would exist, if all the processes of decay were stopped.

"To Err is Human."

But to err all the time is criminal or idiotic. Don't continue the mistake of neglecting your blood. When impurities manifest themselves in eruptions or when disordered conditions of stomach, kidneys, liver or bowels appear, take Hood's Sarsaparilla. It will make pure, live blood, and put you in good health.

Hood's Sarsaparilla
Never Disappoints

Life cannot exist forever; the very processes that are concerned in the development and increase of organic tissue are self-limiting. Growing bulk soon reaches a point, where adequate nutrition can no longer go on, and then growth and nourishment must soon cease, and death finally occur. The process is the same for man, beast or plant. The period of existence, only, may vary some.

Sooner or later, therefore, all living things must die. When dead, no longer do they subserve any special function among living things, unless it is to nourish them for a brief season. The inevitable result that would soon occur then, if the processes of organic decay were stopped, would be the clogging of the wheels of the universe in its own debris. The dead and dying plant or animal that was unused by other forms, would remain a specter of its former being. The leaves of the forest and the grass of the plains would be beaten back to earth, there to accumulate as dried organic matter. Such a state of affairs would soon bury all remaining forms of life beneath a constantly accumulating mass.

Not only this, but life itself would soon be starved out of actual existence. Stop the machinery of decay, stop the formation of available nitrogenous salts in the soil, and soon the continued growth of vegetable matter will begin to weaken, and finally cease, for the lack of proper plant food.

When this occurs, when the green plant can no longer build up organic matter out of the inorganic elements of soil and sky, then animal life is soon doomed. The granaries of the world cannot supply even man for only a year or so at most. Cut off this supply and the animate world is doomed.

Thus we see how important is the office these unseen friends fill, that are toiling away for the good, of not only themselves, but all the rest of the living forces on our planet. Theirs is a humble office, but in their place, they are doing a work that in the economy of this universe has no equal, that can best be done by them. Does not this thought dignify their labor? Does it not invest these "infinitely little," but infinitely powerful agencies with more than passing interest?

Raise Good Hogs.

(Press Bulletin.)

If a person who knows anything at all about hog feeding was given a chance between a hog that would gain twenty-three pounds in six weeks and one that would gain ninety pounds in the same time on the same feed, he would not be long in choosing. During the past ten months the Kansas Experiment Station has fed 190 hogs that were bought of the farmers in the vicinity of Manhattan, without regard to breed or breeding, just as they were, thrifty and weighing in the neighborhood of 100 to 125 pounds. This class of hogs is used because these ex-

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,
67 Main Street, - Cortland, N. Y.

periments are for the highest benefit of the farmers, and by taking the stock they raise we stay within their conditions. A few conclusions may be drawn from the following facts, taken from observations of feeding eighty head of hogs, which were just finished. These hogs were nearer the same age than size, and ranged from the long, big-boned bacon hog to the short, fine-boned chunk, according to the care or carelessness of the farmer who raised them.

First, as to point of gain: The comparisons are between hogs fed the same in every respect. The best and poorest five out of twenty have the following showing:

Best five, weight at beginning of test, 596 pounds, gain 416 pounds.....	70%
Poorest five, weight at beginning of test, 579 pounds, gain, 235 pounds.....	40%

This was for a period of forty-two days, and from observations made from week to week, this difference of gain from a little over one pound to practically two pounds a day was largely due to the breeding. A short, small-boned chunk will make good gains for a few weeks and then stop. It will be fat and ready for market, while a well-bred, rangy hog will fatten and continue to grow and make good gains for a much longer period. Then as to the demand of the market; the three-rib shoulder is now one of the most profitable cuts that is made for export trade. Hogs from which these cuts are made must be large and muscular, long and rangy. The short, small-boned chunk will not answer the purpose. The bacon hog is also of the latter description and brings the best price on the markets. Well-bred, rangy hogs make the most profitable gains, are the most ready sale and bring the best price on the market.

J. G. HANEY.

Kansas Experiment Station.

Florida Beggar Weed.

Florida beggar weed is an erect annual, a native of the West Indies, and perhaps also of Southern Florida. It is a leguminous plant with rather woody stalks from three to eight or ten feet high, bearing an abundant leafage above and when in flower tipped with much branched erect panicles, the ascending lateral branches often eight to twelve inches long. The seeds are borne in many jointed prickly pods, which break apart at maturity, and are carried about by sticking to the bodies of animals or the clothing of persons. The plant is hairy throughout, and has trifoliate leaves, the obliquely rhomboid leaflets being from two to four inches long. Florida beggar weed is closely related to the beggar weeds or beggar lice of northern woodlands and prairies. Being a subtropical species, it is adapted to cultivation, either as forage or for soil renovation in subtropical regions. It now ranks in the estimation of the planter with velvet bean, though perhaps its sphere of usefulness is not so extended as the latter.

HOW TO SOW THE SEED.

For a crop of seed, beggar weed should be sown at the rate of five or six pounds of clean seed per acre. If grown for hay, from eight to ten pounds should be used. It should not be sown until the ground is warm and moist, and the clean seed is preferable to the pods because of the more uniform germination and better stand which may be obtained. The seed is about the size shape and color of red clover and weighs about as much to the bushel. It is now on the market at a price low enough to place it within the reach of any farmer. If sown at the beginning of the summer rains the seed need not be covered. It must not be buried too deeply else the young plants will not be able to reach the surface. By sowing at the beginning of summer two crops may be secured. If cut for hay at the time the first flowers appear, the roots will send up a second crop, which may be saved for seed, and enough seed will scatter to insure a crop the next season. The seed may also be scattered in the corn rows at the time of the last cultivation or at the beginning of the rains in June. Then, after the corn has been stripped or cut for fodder, the beggar weed may be mown for hay or harvested for seed. The crop should be cut for hay when it is about three or four feet high, or at the beginning of the blooming period. If cut after full bloom many of the lower leaves will have fallen and much of the best part of the crop will be lost.

ITS VALUE AS A HAY CROP.

Beggar weed makes a very fine quality of hay, which is relished by all classes of farm stock.

According to analyses made at the Florida Experiment Station, of the upper parts of plants not yet in seed, 100 pounds of hay contained 19.4 pounds of crude protein. When cut after the seed had ripened the crude protein had decreased to 15.75 pounds, the fat and non-nitrogenous extracts from 45.4 pounds to 42.7 pounds, and the crude fiber or indigestible portion had increased from 19.6 to 26.5 pounds. An average of two analyses of the entire plant, including the woody stems, the one made from plants in green seed, the other from those not yet seeding, indicated 11.85 pounds of crude protein in 100 pounds of hay. This may be taken as representing more nearly the crude protein value of average beggar weed hay, than the larger quantity shown to be present in the upper, more leafy, and more tender portion of the plant. If in cutting this crop only the upper leafy parts were saved then the higher percentage of protein might be taken as representing the value.

BEGGAR WEED AS A FEED.

Beggar weed hay may be fed to best advantage by adding to the ration some coarse forage which contains a smaller amount of crude protein and more carbohydrates. In this way all of the digestible portion of the crude protein in the beggar weed may be utilized. If more is fed than can be utilized, that is to say, if the nutritive ratio of the ration is too narrow, the surplus of crude protein will be wasted.

After the seed crop has been harvested, the beggar weed comes up again, the rowen supplying fine pasturage until killed by frosts. It never becomes a bad weed. The seeds do not sprout until the ground is warm, and it may be used as a rotation crop, following early spring vegetables or corn, the seeds remaining in the ground and making their appearance after these crops are out of the way. As a hay plant it is superior to velvet bean on account of the ease with which it may be cut with an ordinary mower. It is also a better crop to sow in orchards for green manure because it is not, like the velvet bean, a climber, and does not have to be kept out of the trees.

This plant is one of the hosts of the root knot (*Heterodora radicola.*) Prof. Rolfs states that the "cow pea is frequently attacked, the velvet bean occasionally, and the beggar weed rarely." The nodules formed by this worm resemble the tubercles formed by the nitrogen gathering bacteria but may be distinguished by microscopical examination.— J.G. Smith in *Southern Farm Gazette.*

Lath and Cement for Lining a Silo.

ED. HOARD'S DAIRYMAN:—In building silo as contemplated by W. A. Barber, on page 470, I think he can greatly improve it by using 5/8 inch lining instead of 3/8. If he uses the former and common plaster lath, nailed diagonally on horizontal lining, being careful to give each lath at least four nails, I will guarantee the plaster to hold. To insure the laths not to bulge after the cement has set, they ought to be well soaked in water before they are put on.

If he has a first-class hydraulic cement, two parts sand to one of cement will do. Still, if I were to build it, I would use a little less sand, it makes a harder job. I don't think the beveled lath will improve it any. Have had experience in use of both and find the common lath better, because cheaper. Let him get a good plasterer to put it on and I am sure he will be well pleased with it.

Weeds and Milk.

An article in the *Farmer and Stock Breeder* of London, says: "The plants which may be considered good for feeding cows will give us no trouble; but these are commonly associated with others which are mischievous. The true grasses and leguminous plants may cause changes in milk quality by their many mixtures, proportions, and growth, but they will not interfere with the dairy processes, or give to the product ill qualities. The miscellaneous plants, which may be considered weeds, include some which are dangerous to the health of the cow; others, more numerous, which flavor milk undesirably; and a few which color milk, or produce irregularities. To these causes of mischief must be added those arising from the plant diseases of a fungoid nature. Do cows eat any appreciable proportion of such plants? The occasions known may be few in which the mischief is recognized and traced to some particular plants, but such do not occur often enough to make the matter one of great importance; and we believe that a very considerable amount of harm is done daily by such weeds as are incapable of giving a distinctly bad flavor to the milk, but in their many kinds combine to give one generally inferior. What is the cure? Clean pastures. If a weed is a pest in a cornfield, it is a much greater one in the case before us, where it not only takes the place of a better plant, and hinders the superior growths around it, but actually does direct damage to the dairyman's goods. Weeds are the natural and almost inevitable consequence of neglect. There are few pastures which can be kept sweet and free from such trouble by the mere force of natural conditions. Draining and manuring can do much in reducing the miscellaneous plants to small numbers and the more innocent kinds, and a constant war against them should be maintained.

ICE AND FLAVOR.

A butter expert writes the following to a creamery man regarding the result of using ice in the cream tank and churn:

"We are finding a great many tubs of butter that have an indication that ice was used in the cream vat or in the churn. I do not know whether you did this or not. If I should make a guess at it, I should say you did, and that you injured the flavor by doing this. If you did not do either of these things then I am at a loss to understand why the flavor is not better."

The DAIRYMAN has frequently been asked regarding the advisability of the use of ice in the cream. It has replied that as ice invariably contained dirt, it should not be added to cream, but that it probably would be used where no other means of cooling cream was at hand.

This use of ice was not advocated from a purely theoretical standpoint, but from the danger which which might come from the addition of the dirt in ice. Now we find that the expert states that it injures the flavor. This should be enough to settle the question as to the use of ice in cream.

TUBERCULOSIS WORK IN NEW YORK.

At the late Annual Meeting, of the New York Medical Association, Dr. Florince O. Donohue, of New York city, read a paper on "State Examination of Milk for Tuberculosis:"

"Examinations made in certain sections of this state," he said, "revealed so extensive a prevalence of tuberculosis among cattle, as to create a very material alarm in the minds of dairy farmers. It is doubtless owing to this hostility, in a large measure, that appropriations were withheld by the present administration for the continuance of the work. The law is still in force, and the commissioners are drawing their salaries, but for the past two years the work has been at a standstill. It must and will be taken up again, for civilization will demand that the product of the dairy shall be free from the germs of a lingering and infectious disease, the most destructive that afflicts humanity."

If Dr. Donohue is right in the above assumptions, which the DAIRYMAN is not yet prepared to admit, there follows another conclusion, equally as strong and convincing as any that he gives; that is, that it is to the vital interest to dairy farmers, to weed out all tuberculous animals from their herds, in order to stop infection and save the capital invested in their cows.

Ayer's Hair Vigor

What does it do?

It causes the oil glands in the skin to become more active, making the hair soft and glossy, precisely as nature intended.

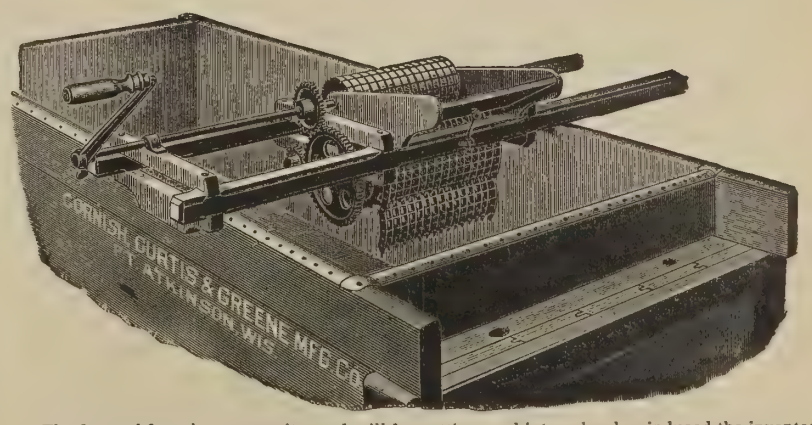
It cleanses the scalp from dandruff and thus removes one of the great causes of baldness.

It makes a better circulation in the scalp and stops the hair from coming out.

It Prevents and It Cures Baldness

Ayer's Hair Vigor will surely make hair grow on bald heads, provided only there is any life remaining in the hair bulbs.

It restores color to gray or white hair. It does not do this in a moment, as will a hair dye; but in a short time the gray color of age gradually disappears and the darker color of youth takes its place.



Would you like a copy of our book on the Hair and Scalp? It is free.

If you do not obtain all the benefits you expected from the use of the Vigor write the Doctor about it.

Address, DR. J. C. AYER, Lowell, Mass.

SHORTHAND Book-keeping, Penmanship, 64-page Illustrated catalog free. Board and tuition reasonable. Situations for Graduates. Address, D. L. MUSSELMAN, President, Gem City Business College, Quincy, Illinois.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentation to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, $25.00

Silo Questions by the Score.

ED. HOARD'S DAIRYMAN:—In your issue of May 19th last, you give details for building silo, from Cornell University Bulletins. I am about to build a silo and the above referred to description has attracted my attention on account of its cheapness. Now, I want to say I am a novice at the silo business in every particular, as I never saw one or fed from one. Therefore, I will be pleased for any suggestions you will make. Do you endorse the kind, and if so, do you also favor the manner of building above referred to? Would you favor a thicker concrete foundation, or thicker staves, or larger iron for hoops, or thicker put on? Also, what kind of ensilage cutter, and where to be got, and what size and price? Also, what kind of lumber, and is there a company where we can get stuff all ready fitted to set up, also the best way to buy the hoops and lugs? If you are not prepared to answer all above questions, or haven't the time, please refer me to proper parties, or send this letter to them. Please give this your early attention and oblige. H. A. B.

Marengo, Ia.

P. S. Silo for about fifty head, cows mostly.

The stave silo is undoubtedly here to stay, and if we were to build one this year, we should follow the directions and plans referred to very closely. Further experience may suggest modifications for next year or other future time, but if one waits for the time when no further improvements are possible, he will never have a silo, and that will not pay. The writer built a silo ten years ago, according to the best light then obtainable. Compared with modern structures it never was a good silo, but all the same it has served a good purpose and is still too good to be torn down or abandoned.

There are several styles of cutters,—none better than those advertised on page 524. The man using any one of these, will be pretty sure to conclude that the one he has is the best. Do not make the mistake of buying too small a machine. The one we use has a 12-inch cut and we have always regretted it was not two inches larger. We are not advised as to present prices. If your local dealers do not handle this kind of machinery, write to these advertisers.

For Iowa, we suppose the only kinds of lumber available will be pine and hemlock. Either can be had from local dealers or the manufacturers of lumber along the Mississippi River, and should be bought, dressed on both sides and jointed on both edges. They may also be had, with beveled edges and grooved, if so preferred.

Get hoops and lugs through local hardware merchants, or dispense with lugs altogether by using two or more pieces of 4×6 in place of the same number of common staves and let the ends of the hoops run through these in place of lugs.

Poor Churning Cream.

ED. HOARD'S DAIRYMAN:—Will you please tell me what ails my cream? Since early spring it has taken from one to two hours to do the churning. Use a bent wood churn, except when a small churning happens, then the small stone churn and its dash is used, and the last three churnings were so hard to gather.

We have four cows which were fresh in February and March and one fresh the first of June, which I had hoped would hurry the churning, but did not. Cows have good pasture, plenty of water and salt, and now a feed of sowed corn fodder, night and morning. Milk is set in crocks in cellar, skimmed night and morning; seldom more than three milkings on the shelves at once. Churn every other and sometimes every day. Temperature in cellar ranges from 60° to 65°. Of course, some of the hottest days it gets a little higher. Never had such trouble before and have made butter for the last nine years in the same cellar, giving milk and cream the same care. A. B. A.

Owasso, Mich.

The trouble with your cream may be due to the cow, food or species of ferment present in the cream, but the chances are that it is due to the ferment in the cream and its action on the casein and milk sugar. If your cream showed but little or no acid when it was ripe for churning, it would be a good proof that the trouble was in the cream and not in the animals or feed.

The proper ferment when ripening cream should at the same time form several tenths of a per cent of lactic acid.

The presence of the acid coagulates the casein and causes the cream to become less viscous, thus making the churning easier and more thorough.

If the acid ferment is not present and its place is taken by neutral or alkali forming ferments, the cream will become more viscous and the churning harder, as may be the conditions of your case. Except when the cows are far advanced in lactation the cause of poor churning is almost always due to the action of bacteria of the neutral or alkali forming species.

The remedy is to introduce the normal lactic acid species by a thorough cleaning of all dairy utensils, scalding with hot water and soda, and after everything has been given a good cleaning, pasteurize the first lot of cream, and add a good clean starter from some dairy in the neighborhood, or by means of one of the artificial starters. If the proper ferment is introduced there should be no trouble with the churning. In cases like the above the determination of the amount of acid in the cream by means of Farrington's Alkaline Tablets would quickly show where the trouble is and save their cost many times over by locating the source of the loss of butter fat.

Going to Texas.

ED. HOARD'S DAIRYMAN:—I began taking your paper last January, and am well pleased with it.

We commenced selling milk to the Hamilton creamery, a year ago last November, and have continued to do so, regularly, ever since. Prices paid have ranged from 50 cents to $1.00 per hundred. Everything considered, I am well satisfied with results. I have sold out here and intend to move to South Texas the coming fall, seventy-seven miles west from Houston, and sixty miles from the coast.

I intend to start in the cattle business in a small way and, as I am inexperienced, I would kindly ask for a little information. Which would be more profitable, raising cattle for beef or dairy? It is my purpose to start with about twelve or fifteen cows. As there is no creamery yet at the place to which we are going, (Rock Island) we will have to manage the milk at home.

What is the feeding value of prairie grass and of prairie hay? Cow peas, oats, millet, sorghum, etc., do well down there, but I don't think clover and timothy will succeed well. Alfalfa is also grown. Any information you can give me will be thankfully received. My means are small, and I will not, perhaps, be able on the start, to purchase a hand separator, or build a silo. W. C.

Hamilton, Mo.

From the best information we can obtain, we believe that in anything like favorable localities, there is no industry in Texas that pays better than up-to-date dairying. But there, as elsewhere, one must adapt himself to the markets and the means of reaching them. Neither milk nor butter will stand a long haul by wagon, but one can drive hogs or steers almost any distance. A Texas town of 1,000 or more inhabitants, of a class accustomed to use milk and butter freely, and a farm within six miles of it, would seem to justify a venture in dairying with a herd of twelve to twenty cows—provided they are good ones. But do not make the mistake of trying to have a general-purpose herd, if it is expected to make any money out of milk. Get and keep only high-class dairy cows, and then, if it is desired to do something along beef lines, buy beef bred calves. This will be much cheaper and more profitable than any other course that can be pursued.

The Holstein-Friesian Association's Proposition to Other Dairy Cattle Associations.

The Holstein-Friesian Association of America hereby extends greetings to all associations of breeders of pure-bred dairy cows, and invites them to participate in a competitive prize contest for the production of pure butter fat; such contest to be conducted upon the following general plan:

1. All tests and awards to be under the direction and control of a committee to consist of officers or representatives of Agricultural Colleges or Experiment Stations.

2. Each breed competing shall select one member of the committee.

3. All tests shall be conducted at the homes of the animals by a representative of an Agricultural College or Experiment Station, and shall be made by employing the Babcock test.

4. Awards shall be for the highest production of pure butter fat per cow, and for periods of not less than seven consecutive days.

5. Each association competing to contribute a like sum of money, not less than $500.00 each, and from the aggregate sum so contributed the prizes are to be awarded

6. Cows shall be divided into classes according to age.

7. It is recommended that four prizes be offered in each class, with not less than four cows in each class.

8. All tests to be made within a year from a date to be agreed upon; and all entries shall be made, prizes awarded within three months after the expiration of the test year.

9. The entries made from each breed shall be subject to the approval of a representative selected by each association.

10. All further details as to the division of the prize money, and necessary to carry this plan into effect, to be agreed upon by a committee consisting of three representatives from each association competing.

11. This proposition to be accepted by each association intending to compete, on or before the first day of December, 1899.

Holstein-Friesian Association of America.
F. L. HOUGHTON,
Secretary.

Running Separator by Water Power.

ED. HOARD'S DAIRYMAN:—Would like to hear from those having experience in running cream separators by water power. Can supply 100 gallons per minute. Will have to run it 1,000 feet through pipe and can give it twenty foot fall. Anything that will enlighten me will be thankfully received.

Fairfield, Utah. C. J.

Ensilage Carriers.

EDITOR HOARD'S DAIRYMAN:—I notice in this week's issue of the DAIRYMAN some inquiry in regard to a better way to run an ensilage carrier. I have run mine for several years from the top end by the use of a rope belt, and am satisfied it does not require more than one-half as much power as to run from the bottom end with sprocket chain. My carrier is thirty feet long with one chain in center. Slats are bolted on with tire bolts to sprocket links made for the purpose; they can be bought or ordered at any machine shop. The chain is common binder chain No. 45. Use sprocket wheel to pull carrier chain at top of carrier and smooth roller at bottom. Have slide under carrier for chain to return on. My pulleys for rope belt are home made of inch boards nailed together. Use nothing smaller than ¾ inch rope. A. F. G.

Harrison, Ill.

Making Good Butter Without Ice.

It is true that there is considerable difficulty experienced in attempting the manufacture of really fine butter in summer without the aid of ice.

Temperature is an all important factor in determining the quality of the product during the hot weather, and ice is almost indispensable in order to secure the proper degree of cold for the successful termination of one's efforts. Yet, with due care and labor, a very good article may be made without using ice.

It is hoped that the majority of farmers throughout the Northern states put up a supply of ice for summer use, yet not all do, and the wife is often handicapped in her dairy work thereby.

The first thing necessary in order to secure good butter, without the aid of ice, is a good cellar. This should be perfectly clean and free from everything which might in any way contaminate the air. All decaying boards, vegetables, no matter in what state of preservation, should be removed and the walls whitewashed, or washed over with a solution of copperas and water. Thoroughly disinfecting every portion of the cellar is a necessity.

Provide racks for the milk pans and have the latter of bright new tin, which is the best material. Discard any which are old and rusty.

Skim when just turning sour and keep the cream in the very coolest portion of the cellar. Churn every other day.

To cool the cream sufficiently, set the vessel containing it in a tub of cold water in the cellar over night. Have a woolen blanket wet in cold water to lay over the top. This keeps out the warm air and tends to keep the cream cold.

The churn should be well cooled with water also. Churn the first thing in the morning.

When the butter shows signs of coming add a handful of salt and several quarts of cold water, according to amount of cream, to reduce temperature. Take out the butter, or draw off the buttermilk as the case may be, and wash thoroughly in water as cold as can be obtained. Do not churn too long but stop when the butter is in grains, before it is gathered into a lump.

After washing until free from buttermilk, salt according to taste. Work the salt in thoroughly and evenly, pressing with the ladle to exclude moisture, then set away to harden again before reworking very lightly, so as not to injure the grain.

A person determined to succeed in making fine butter will manage in some way to accomplish it, if she has to hang the cream in the well to get it cool enough to churn.

Utmost cleanliness must be observed in every detail. The milk things must be kept perfectly sweet, everything free from the taint of odor.

The nose should play a most important part in detecting anything wrong about the dairy work. It is a valuable agent in doing detective work, and an observing eye should always be kept over each particular point from start to finish.

The great bulk of butter still comes from the farm, and good or bad, the farm butter makers must stand responsible for it. If each would try her best to improve the quality of her own, what a difference might be noted in the next year.

Advice in this letter to set milk in pans in the cellar is given on the assumption that the person advised has no portable creamery, and is still using the common round pan. But to a person who has a creamery and is out of ice, my advice is to use as cold water as can be had, changing it fully as often as it equalizes temperature with the milk. However, to those farmers who are without ice and improved apparatus for cream raising, I would repeat advice, to set milk in cellar.—*Nebraska Farmer.*

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—But two lots of butter were offered for sale on Monday's Elgin Board of Trade, and both were sold at 18½ cents. More was in demand but was not forthcoming. The Quotation Committee declare the market firm and fixed the marker price at 18 cents. The sales of the week were 11,200 pounds.

The call sales of Monday were:

Factory.	*Pounds.*	*Price.*
Spring Prairie	2,100	18½c.
Dundee	1,200	18½c.
Total	3,300	

The sales for the corresponding week of the three preceding years were as follows:

Aug. 8, 1889, 9,840 lbs. of butter sold at 18½c.
Aug. 9, 1897, 21,000 lbs. of butter sold at 15c.
Aug. 10, 1896, 24,300 lbs. of butter sold at 15@15 1-5c.

Elgin, Ill., Aug. 7, 1899. H. C. B.

DAIRY MARKETS.

ELGIN, Ill., Aug. 7.—Fifty-five tubs offered; all sold 18½ cents; official price, firm, 18 cents.

CHICAGO, Ill., Aug. 7.—Butter—Creamery, extra, 17¼@17½c; firsts, creameries, 16@16½c; seconds, 14@15c; dairies, selections, 15@15½c; No. 1, 14c; No. 2, 12½c; extra ladles, 13@13½c.

Eggs—Fresh, at mark, cases returned, sold at 10½@11c loss off, cases returned, 12½c.

Cheese—Full cream, twins, new, good to choice, 9@9¼c; Limburger, 7@8½c; bricks, 8@9c. Young America, 9½@10c; Swiss, 8@10¼c.

Bran—In moderate demand, and sold at $10.-50 per ton f. o. b., and $10.25 billed through.

Middlings—Quiet and sold at $11.50 per ton on track.

Cattle—The market was generally steady, with good to choice cattle at the high point of the year. Native beeves sold at $4.50@6.05. Ten cars of Western range cattle sold at $4.90, with one load at $5.25. Texas-fed steers sold at $4.50 @4.80, with Texas grassers at $4.05@4.50. The market for inferior heifers and butcher stock was weak. Other grades ruled steady.

Today's receipts are estimated at 2,500.

MILWAUKEE, Wis., Aug. 7.—Butter—Creamery—Fancy prints, per lb. 17½c; extras 17½c; firsts 16@17c; seconds 14@15c; imitations 14@15c. Dairy—selections per lb. 14@15c; lines 12@13c.

Market strong and well cleared, trade being brisk; receipts 8,990 lbs.

Cheese—American Full Cream—New choice to fancy 9@9½c. Brick—New, per lb. choice 8@8½c. Limburger choice, per lb. 8@8½c. Swiss—Drum, choice 12½@13c; new block, choice 10@10½c. Market firm; receipts 44,800 lbs. Trade fair.

Eggs—Fresh, per doz. 11@11½c; loss-off cases returned. Market unchanged, with receipts of 289 cases; trade moderate.

MUSCODA, Wis., Aug. 7.—Offerings to-day on the dairy board were 1,700 boxes cheese; market quiet at 8⅞@9c. One car Twins, 9⅛c; ninety daisies at 9⅜c.

FOND DU LAC, Wis., Aug. 7.—Offerings, 618 twins, 425 Daisies; market strong; Twins, 9¼c; daisies, 9¾c.

PLYMOUTH, Wis., July 31—Cheese—Sales today 1,200 Twins at 9¼c; 75 Twins at 9½c; 825 Americas at 9⅜c.

HILBERT, Wis., July 29—Cheese—The sales on the call board today were 50 Twins at 9c, and 117 cases Young Americas at 9c.

BRILLION, Wis., July 28—Cheese—Sales cheese, Brillion Dairy Board, 1,230 Daisies, 1,057 Twins, 435 Young Americas; market 9c, one lot sold at 9⅛c, one at 9¼c.

SHEBOYGAN FALLS, Wis., Aug. 2.—There were 966 boxes of cheese offered on the call board to-day and all were sold as follows: 695 cases of Young Americas at 9⅞c; 136 twins at 9¼c; 35 at 9⅜c; 35 daisies at 9⅞c and 140 at 10c; market active.

MANITOWOC, Wis., Aug. 2.—Offerings of cheese at the Dairy Board to-day were 900 boxes daisies, 120 boxes twins, 900 boxes Young Americas. All offerings sold at 9c.

NEW YORK, Aug. 7.—Butter—Market firm and 18½c was paid for best Western creamery.

Cheese—Market firm but quiet; in some cases 9½c was asked for large, fancy, white cheese, but 9¼c was generally quoted; state full cream large white fancy, 9¼c, and small white, 9¼c; large colored fancy, 9½c; small colored fancy, 9½c; state light skims small choice, 7¾@8c, and large choice, 7½@7¾c; state part skims small and large choice, 7@7¼c; full skims, 3@3½c.

Eggs—Prices were ½c higher today on fresh eggs, with buyers very discriminating and not much strictly desirable stock offered; Northern Indiana, Ohio and Michigan, 15½c, loss off; average Western, 10@12c, case count; Southwestern best, loss off, 9@10c, case count; dirties, 30 dozen case, $2@3 as to quality; checks, per case, $2.@ 2.40.

WATERTOWN, N. Y., July 30—Cheese—The cheese market here yesterday, was very active. There were 500 boxes offered and sold. The prices ranged from 9⅛@9¼c. The Canadians took the bulk as usual.

CANTON, N. Y., July 29—Cheese—2,200 boxes cheese sold at 9¼c.

Butter—1,300 pkgs. butter at 18¾c.

LITTLE FALLS, N. Y., July 31—Cheese—418 boxes large cheese sold at 8⅞@9c; 208 boxes on private terms; 5,263 boxes small at 9c.

UTICA, N. Y., July 31—Cheese—5,072 boxes large, colored cheese sold at 9@9¼c; 453 boxes large, white at 9@9½c; 720 small colored at 9¼c; 1,335 small white at 9@9⅜c.

BOONEVILLE, N. Y., July 30—Cheese—All the sales of cheese on the market, Friday, were curb transactions. There were 1,042 boxes sold at a range of from 9@9½c.

WASHINGTON, D. C., Aug. 7—Butter—Market steady, extras 19c; firsts 18c; seconds 16@17c.

BOSTON, Mass., Aug. 7—Butter—Very firm, 18@19c.

Cheese—Market firm, 10½c.

Eggs—Unsettled, 14@15c.

NEWARK, N. J., Aug. 7—Butter—Market firm; 18½@19c for fancy Elgin creamery. Receipts liberal.

SAN FRANCISCO, Cal., Aug. 7—Butter—Firm, creamery 15@18c; dairy 12@15c.

BALTIMORE, Md., Aug. 7—Butter—Market firm. Creamery, separater, extra 20c; extra firsts 18@19c; creamery, firsts 17@18c; creamery, imitation, extra, 16@17c; ladle, extra, 16c; Western, store-packed, 12½c.

Eggs—Market firm; strictly fresh stock, 12c.

PHILADELPHIA, Pa., Aug. 7—Butter—Solid packed separator creamery, extra, 18½@19c; creamery, firsts, 18c; seconds, 16@17c; imitation creamery, extra 16c; firsts 15c; seconds 13c; ladle packed, extra 14@14½c; firsts 13½c; seconds 13c. Print butter, creamery, extra, 21c; firsts 20c; seconds, 18@19c.

Eggs—Pennsylvania and near-by, 14c; Western, 14@14½c; Southwestern 13c; Southern 10@11c.

ST. LOUIS, Mo., Aug. 7—Butter—Firm: creamery, 15@18c; dairy 12@15c.

Eggs—Quiet, 9c.

KANSAS CITY, Mo., Aug. 7—Butter—Creamery, 14@16½c; dairy, 14c.

Eggs—Fresh, 9c.

CINCINNATI, O., Aug. 7—Butter—Quiet; 19c.

Eggs—Dull; 9c.

Cheese—Good demand; good to prime Ohio flat, 8¾c.

Latest quotations for fancy creamery: Buffalo 18½c; St. Paul, 17½c; Minneapolis, 18c; Detroit, 19c; New Orleans 18½@19c.

LIVERPOOL, Aug. 7—Butter—Finest United States 88s; good 65s.

Cheese—American finest colored, 45s, American finest white 45s.

BALTIMORE MARKET.

BALTIMORE, Md., Aug. 3—Butter—As far as reported, the past week was devoid of interesting features; there was not as much exporting done as during the previous week, and out of town buyers, with a few notable exceptions, remained out of town. The receipts of separator creamery are as full as usual at this time with the grading equal to the past; it is quite likely that some lines will not find immediate sale and largely for two reasons, the one being that the quality is not phenomenal, and the other that some gathered cream makes will answer many purposes reserved for separators at other times. The latter variety of butter is in lighter receipt and the majority of the regular marks have evidenced the advance of the season; for, although it is the general verdict that such a pleasant summer has not been vouchsafed to beast and man, lo! these many years, nevertheless, the August peculiarities that impress themselves so objectionably upon the product of the churn during dog days, are again to be met with in most parcels, and this is said to be true of the past by actual observation, covering a period of years beyond which the memory of man runneth not to the contrary, and whether the dog days are very much so or otherwise. Imitation creamery receipts are at the lowest ebb and high grade ladles are no more; the best of the latter are far from fine, but the quantity arriving is so small that receivers are encouraged to continue the same selling prices, and somehow or other there are none left over at the end of each week. Prints and blocks are in fair receipt and equal demand; there is some fair business doing in factory makes. Storepacked is in light receipt and has a quick demand; quality is poor.

Creamery separator, extras, per pound, 19c; firsts, 18c; seconds, 17c; gathered cream, extras, 17@18c; firsts, 17c; seconds, 16c; Ohio, extras, 17@18c; firsts, 17c; seconds, 16c. Iowa and N. W. ladle, extras, 14c; firsts, 13c; seconds, 12c. Ohio and Indiana ladle, extras, 14c; firsts, 13c; seconds, 12c. Ohio storepacked, extras, 12½@13c; firsts, 12c. W. Va. storepacked, extras, 12½@13c; firsts, 12c. Creamery blocks (2 lb.), extras, 21c; firsts, 20c; seconds, 19c; prints (½ lb.), extras, 21c; firsts, 20c; seconds, 19c. Md., Va. and Penna. prints, extras, 19c; firsts, 18c; seconds, 16@17c.

Cheese—Receipts of cheese continue light; the demand is fair; market firm.

N. Y. State Cheddars, fine, 9¾c; choice, 9¼@9½c; fair, 8½@8¾c; Flats, fine, 9¾@10c; choice, 9¼@9½c; fair, 8½@9c; Small, fine, 10¼@10½c; choice, 9¾@10c; fair, 9@9½c. Ohio Flats, fine, 9⅝@9¾c; choice, 9@9¼c; fair, 8½@8¾c; picnic, fine, 9½@10c. Swiss cheese, fine, 11@12c; choice, 10½@10¾c.

Eggs—The receipts of choice fresh eggs are light; the supply of this kind is not sufficient to supply the demand, consequently our market is kept bare of all choice to fancy eggs, while all doubtful and tender stock is hard to sell and the supply is accumulating. First quality brings 11@12c. G. M. LAMB & BRO.

391 Exchange Place.

NEW YORK MARKET.

NEW YORK, August 5—Butter—Receipts for the week, 43,504 packages. Exports for the week, 11,819 packages.

The market has ruled steady all the week under fair trading from all quarters and at the close there is less extra creamery offering and a disposition to ask trifle more price. Our local trade buy only the tip top quality; receipts this week have shown little of this style of butter, and some of the best marks were bid up ¼@½c per pound. Exporters have bought steadily of good to fine creameries at 17@17⅛@18c, paying the last price for strictly fancy goods. We note sales for Eastern account of several hundred tubs fancy creamery at 18c. Very little fine dairy arriving, hardly enough to supply the demand or establish a quotation. Ladles quiet but firm. We quote: Creamery, extra, 18c; medium, 17@17½c; poor, 14@16c. Dairy, extra, 17@17½c; medium, 16@16½c; poor, 14@15.

Cheese—Receipts for the week, 38,783 boxes. Exports for the week, 10,632 boxes.

Market was active and strong through the early part of the week, both exporters and home trade buying liberally at full prices. At the close there is less motion with exporters out of the market and a general feeling among the trade that prices are high enough for the present. Sales in the interior of the state were about same prices as here. We note sales at Catteraugus yesterday of Cheddars at 9½c and small cheese at 9¾c. We quote:

Full Cream, large, extra 9½c; medium 9@9¼c; poor 7@8c. Full Cream, small, extra 9¾c: medium 9@9½c; poor 7@8c. Part Skimmed, extra 8@8½c; medium 7@7½c; poor 5@6c.

Eggs—Receipts for the week, 50,642 cases.

Strictly fresh eggs have good demand at full prices. Other grades are extremely hard to sell, and prices are irregular and nominal. We quote: N. Y. & Penn., finest, per dozen, 15½@16c; Northern & Western, 15@15½c; Other sections, fair to good, 12@13c. DAVID W. LEWIS & CO.

177 Chambers St.

FOREIGN MARKET.

BOSTON, Mass., Aug. 5—Cable advices of this date, from the principal markets of Great Britain to Geo. A. Cochrane, gives butter markets as firm, more active and higher on finest description of well conditioned parcels. The great activity has been in Canadians, which have been increasing weekly in favor with buyers. The landing condition of it is in strong contrast with all home and Continental butters. The quality being very superior, and with its freshness has made it the most popular butter offering. The weather has been hot, and the landing condition of all Continental and Irish butters has been dreadful, in a large number of cases, the butter being badly injured. Good conditioned parcels of Danish have sold as high as 22@23c, but a great deal is offering at 18@20c on account of its condition. The same may be said of Irish; hardly any is good enough to bring 20@21c, but a great deal offering at 16½@17c. Some American creameries, in tubs, have sold at 18@19½c, very little of it being fine enough to command the latter price. So much out of conditioned Continental, Irish and home made butter interferes with its sale greatly. Ladles have ruled inactive and dull as so much heated stuff is being pressed for sale, has caused a temporary lull in the demand for ladles. What little is selling brings from 14½@15½c. Imitations are a very dull sale.

Cheese markets have again advanced and are in a very healthy condition. The large consumptive demand continues to absorb receipts as fast as landed, and there are no accumulations. Finest American and Canadian have sold at 10@10½c, with occasional sales of some very fine Canadian at 10¾c. Anything that can be sold from 9@9½c is in active request.

MANCHESTER MARKET ENGLAND.

There are no signs of animation in butter business. The great heat has conduced to present inactivity, but at time of writing, rain has begun to fall in Manchester. Newcastle opened the week with larger arrivals, and quiet but steady consumptive demand, which would likely clear arrivals. Manchester was steady at improved rates, and all choicest cleared, the shortage to this market being still remarkable, nearly 1000 casks less than same date last year. Liverpool cleared well at good prices, but London operations in butter were cautiously conducted, higher prices and the heat causing retailers to buy sparingly. The Scotch markets were slow. Leith is described as having been very dull, demand limited, and a disappointing week. At Glasgow, the fair holidays interfered with business. Spot markets all round have generally similar experience, any firmness that exists being in free on board business. Choicest quality is scarce, and prices are therefore maintained. The Danish official top quotation is unaltered, so also is that of Hamburg, which is very firm at 105 marks. Irish Centrifugal creameries of best sorts are in excellent demand, but there is much soft and even "flowing" butter. Copenhagen says supplies are only equal to demands, production decreasing, several thunderstorms have refreshed pastures, but farmers nevertheless complaining of drought. Cork market rates have been steady on the week, 1sts, 2nds, and 3ds are advanced today 1s, being 80s, 79s and 76s in market respectively. Superfine rose 2s, and are now 85s. Fine milds 73s. Canadian creameries are in very fair request in most markets, as they are very useful at present rates, but best sorts are rather scarce. Our latest American advices received this morning describe their principal markets as closing for the week ending 14th inst. decidedly tame, while no drop in value of "extra" creameries there is an undercurrent of weakness noticeable in first and second qualities which are accumulating on receivers hands. Small experimental shipments will shortly arrive on the English markets, and further business depends on results obtained. Scandinavian shipments at sea and Finish arrivals are 21,979 casks, or about 1,000 more than last week. An improvement is noticed in bulk of sales of margarine mixtures and margarines. No change in prices as yet. DOWDELL BROS.

WHY?

Nine out of every ten experienced separator users use "ALPHA" Disc machines only.

Can there be but one reason for it? Is there any room for doubt as to that reason?

Could there possibly be any stronger testimonial to the practical superiority of the "ALPHA" disc machines than is afforded by this fact.

If you lack experience in the purchase and use of up-to-date Cream Separators can you not safely follow the practice of nine out of ten of those who have acquired such experience, many of them at large cost to themselves?

A De Laval Catalogue—"Factory" or "Dairy"—will be found to throw a flood of light upon separator differences. It may be had for the asking.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada 32-52

Wanted—An all round dairyman. Must be a good buttermaker and understand feeding cows and calves. Single man, steady employment. Address LEE WARREN, Bozeman, Mont.

For Sale—Bull calf, Combination blood, $20.00. Send for pedigree. JOHNSON STOCK FARM, Osceola, Ark.

Wanted—Two-horse tread power, second hand, and second hand shredder, good repair. Address JOHNSON STOCK FARM, Osceola, Ark.

Wanted—A location for a creamery in N. Y. or Northern Pa. 300 or 500 cows. C. E. ANGELL, Speedsville, N. Y.

Wanted—An expert Northern dairyman, graduate of Wisconsin Agricultural College, and of life-long experience, wants position in charge of southern dairy farm. Will work for salary or on shares, and furnish A No. 1 references. Address E. O. THORSGAARD, Streator, Ill. 26-3

Wanted—A first-class butter maker and milker. Address, giving references and stating wages, OLIVER GATES GRIDLEY, Mycenae, N. Y.

Wanted—A good all round farm hand and dairyman. Must be a first-class milker. State references, ability and wages. BOX 120, Mt. Pleasant, Ohio.

Wanted—Prices, pedigree and records on registered young stock, both sexes, Holsteins, Guernseys and Jerseys. AUG. SPOENEMANN, Oakdale, Ill.

Wanted—Man and wife to milk forty cows. Must be speedy and clean milkers. Man to care for cows in winter and in summer to work on farm between milkings. References as to character and ability required. State wages and references. LEWIS E. MURRELL, Lynchburg, Va. 26-2

Excursion Tickets to Annual Regatta, at Oshkosh, Via the North-Western Line, will be sold at reduced rates from stations in Wisconsin, August 13, 14, and 15, limited to include August 21. Apply agents Chicago & North-Western R'y.

Excursion Tickets to the Great American Exposition, to be held at Omaha, Neb., until October 31, 1899. Via the North-Western Line, will be sold at reduced rates. from certain stations on specified dates. For rates, dates of sale and limits of tickets apply to agents Chicago & North-Western Railway. 22-sp

Dairy Notes from Washington.

ED. HOARD'S DAIRYMAN:—While I am absolutely in favor of every honest method and measure by which the fraudulent sale of oleomargarine as butter may be stopped, or at least checked, still I cannot help wondering somewhat at these tremendous efforts to pass laws by which the object may be reached. It certainly cannot be denied that if such laws, as exist in this line in a large number of states, were introduced also in those states where no restrictions as yet have been passed, then indeed there would be no need of any ten-cent tax,especially for colored oleo, because colored oleo simply could not be sold.

How is it in other countries? Denmark, for instance, has excellent laws in this line, which makes it simply impossible to sell oleo except under its true colors; the chance to escape detection is too small and the risk in trying to go against the law too big to make it worth while. At the same time it cannot be denied that enormous quantities of oleomargarine are sold in Denmark and other countries, and over here we love to ridicule the practice that the Danes export all their fine butter, and then, even on the dairy farms, substitute oleo.

But please consider for a moment, that the manufacture of that article also is under such absolute and perfect control, as to only pure and healthy stuff being used in its manufacture, and while I suppose it is true that it is harder to digest than good butter, still I am confident that is as digestible as lots of other stuff we eat without hesitation.

It is of no use to tell a poor man that he must buy fine butter for his family because oleo is hard to digest; he simply can't do it. It is just like advising poor city people to buy pure milk at eight cents a quart (or more) instead of drinking stale beer, bad tea and coffee, etc. The ten-cent tax on colored oleo is O. K., provided it can be enforced if it becomes a law.

But when we claim, that it will in reality stop the manufacture and sale of oleo as such, simply because the people will not buy it knowingly when it looks white as tallow — then I believe we deceive ourselves and make false calculations. I admit that the white appearance of the article temporarily will put a big check to the sales over here; but mark it, such a check will only be temporary.

If the oleo manufacturers will do the wise and straight thing, they will not only comply with the law, but use only pure and honest raw products in the manufacture and insist upon strict government inspection, so that it may be in a position to guarantee pure goods and a cheap price, and white oleo.

If this is done it will only be a question of time for the classes of small means, as to when they shall become accustomed to eat white oleo.

I believe we hardly doubt that the quality of our creamery butter will improve gradually year by year, and at the same time the demand for pure, fancy butter will grow. And, therefore, I believe that oleo sold as such, even of comparatively good quality, will rather advance than hinder the progress of the dairy industry.

It will here, as in Denmark, make the production of inferior butter an impossible business, and necessitate the result here as there, that only fine butter will be made. It will simply compel our buttermakers to work towards the top or get out.

PRESERVATIVES, ETC.

If it is not for the gain that may be had out of a big advertisement, I should like to know why Chicago Produce is so anxious to induce its readers to use preservatives of any kind in their butter? I also would like to know how many and which creameries use the stuff?

It seems to me that any first-class butter maker would feel ashamed to admit that he needs such help to give his butter the necessary keeping quality. I would like to see some creamerymen come forward and openly announce themselves as using such suspicious helps, and who are willing that their buyers should know it.

I think we have yet to find the first case of that kind. And, if neither butter makers nor commission men are willing to have their names published, as using and advocating the use of preservatives, just so long it is plain that these frauds are looked upon as deceptions.

By the way, which manufacturer openly admits that he produces coal-tar butter color? If all right, why then say so, and don't hide.

MISTAKES AS TO BUTTER ADULTERATIONS.

It will be remembered that a few years ago it was claimed by English chemists that Danish butter imported to England had been adulterated by admixtures with foreign fats; it was then proven, by a careful examination of these suspected butters, at the place of production, that certain conditions of the milk, caused from period of lactation, certain feeds, etc., could cause butter to appear to be adulterated.

Lately,in Germany, the wife and daughter of a well-known farmer had been condemned to one week in jail for such adulteration, their butter having been proven to contain from 30 to 40 per cent foreign fat. Prof. D. Dietrich,at Marburg, has now examined said butter at the place of production, and found it to be natural, the irregularity in its character simply being caused from certain feeds; which proves the need of great carefulness.

BUTTER FROM PASTEURIZED SURPLUS CREAM.

While I always have had implicit confidence in the general superiority of butter made from pasteurized cream over that made from raw, yet I have never thought much about the advantages of pasteurization, when the question was of small farm dairies, where the farmer's wife makes the butter of whatever milk or cream can be spared, and where most of this butter is used in the family.

But what happened to me lately, set me to thinking on this point. For the first time since our Sanitary Milk Laboratory has been in operation, I found myself over stocked with cream; as a number of our customers had left rather sudddenly for cooler climes,and a new shipment of cream had arrived, while I yet had about four gallons on hand. If I had returned the older cream by rail road, to our shipper for churning, it would mean throwing railroad freight away.

So I decided to churn it here, though I had neither churn nor butter worker; no, not even a bowl or a paddle. But I will first tell about the cream. It was all five days old, and a small amount several days older had soured, having been exposed to heat; but all of this cream had originally been shipped here by railroad, being separated from evening's milk at a creamery located between Philadelphia and Baltimore. It arrived here, at our laboratory, about noon the following day, being shipped that morning at a temperature of below 40° F., on arrival here being about 56° F. Of course, the can is jacketed, but it is shipped in the hot express car, and twice transferred on the trip.

Upon arrival here the cream is at once pasteurized at 158 or 160° F., as I as yet have not the means to heat higher, without causing cooked flavor. The cream is then, for about an hour, cooled by running hydrant water, then placed in ice-water and cooled below 50° or even to 45°F.

Then it is bottled in sterilized pint and half pint Common Sense bottles, the caps paraffined, and the bottles with cream are then placed in a refrigerator and kept below 50°.

It was a lot of such treated cream I had on hand. I was going to make this into butter, and I made up my mind to make fine butter, too. I emptied all bottles, in one of our Common Sense coolers, and left it till next day in a warm room; next morning it was about 65°. I added about one half gallon freshly clabbered milk, which I had ripened for a starter, and left it for ripening till next morning; then cooled it down to 50°F. by setting in ice-water in a tub, and left the cooler standing in the cold water, as the room was warm.

The churning was done with the dasher I use for stirring cream when heating and cooling, and it was, sure enough, old-fashioned, dash churning. It took me forty-five minutes hard work to make about eleven pounds of butter. How did I finish the job? Well, I stopped in good, up-to-date style when the butter had formed in nice granules, then added a little cold skim milk, took the butter out with a tin sieve, (I like a hair sieve best,) put it in a tub with water of 50° temperature, stirred with my hands, having prepared these well in good, old-time butter makers' fashion, by washing in hot, and rinsing in ice-water, pressed it together in two balls and worked it by hand in a wooden tub, which had previously been well scalded, and then cooled with ice-water; last floaty grains of butter were taken out of the water with the sieve, and no butter was wasted either in the buttermilk or water; the amount made shows that not very much fat was lost even by this curious way of churning, as we were to use all in our family.

I was too lazy to work it twice, as it would have been a good deal more trouble; so the finished butter showed some mottles, as I knew it would. One more light working after an hour or so would have remedied that. But as to *flavor* and general character, the opinion was unanimous, that we never had as fine butter in Washington. But the main point to which I wish to call the "small" butter maker's attention, is the fact, that while this butter lasted us two weeks, still it tasted as fine flavored the last day as the first. I have never bought any butter in the city which would do that, and there is only one explanation.

PASTEURIZATION DID IT.

When in Baltimore I several times churned some small amounts of surplus cream, but it was raw cream, and while never half as old as this, not once did I succeed in making a real, fine flavored butter.

I have here again churned about two gallons pasteurized cream in similar manner, and had the same excellent result. This seems to prove to me, that it would pay, in a small dairy, to pasteurize the cream until enough is on hand for churning; then ripen all, and churn at a low temperature. The result, certainly, would be a great improvement in the butter, and especially in its keeping quality. I should like to see anybody make a fine flavored butter from cream over a week old, if such had not been pasteurized. At least, I should like some progressive dairy women, readers of HOARD'S DAIRYMAN, to try it, and then report the results. It may be a little trouble to pasteurize, but then you may choose any time that suits your convenience for churning, which will be a great point for many.

A COMBINATION OF MARYLAND DAIRIES

for the supply of sanitary and pasteurized milk and cream for Baltimore is contemplated. Some of the most prominent dairies have already entered upon an agreement, among these the well known Filston Farm, and about forty more are expected to join. I consider these combinations of dairies the most sensible step, both to improve the quality, and lessen expense in distribution. When I have more details will report.

J. H. MOLDENHAWER.

Washington, D. C.

An Examination of the Foreign Butter Exhibited at the Green Bay Meeting.

ED. HOARD'S DAIRYMAN:—At the suggestion of Commissioner Adams, I send you herewith the results of my examination of fifteen samples of butter, bought upon the English market, by an agent of the U. S. department of Agriculture, and which were exhibited at the last meeting of the Wisconsin Dairymen's Association.

Tag No. 2.—Danish Creamery, salted. Made Dec. 30th, 1898. Preservatives absent.

Tag No. 3.—Swedish Creamery, salted. Made Dec. 24th, 1898. Borax, moderate amount.

Tag No. 7.—Danish Dairy, salted. Made Dec. 23d, 1898. Preservatives absent.

Tag No. 10.—Irish Dairy, salted. Made in Co. Kerry, Nov. 20th, 1898. Borax, doubtful, heavily salted.

Tag No. 25.—Irish, or Estates Butter. Blended in Cork Dec. 28th, 1898. Boracic acid and Borax, large amount.

Tag No. 27.—English, fresh rolls. Made Dec. 29th, 1898. Preservatives absent.

Tag No. 5.—Friesland Creamery, salted. Made Dec. 23d, 1898. Preservatives, absent.

Tag No. 15.—Australian Creamery, salted. Made Oct. 1898. Borax, moderate amount.

Tag No. 18.—Australian Creamery, salted. Made in N. So. Wales, Oct. 1898. Borax, large amount.

Tag No. 22.—Australian Creamery, salted. Made in Victoria, Sept. 1898. Borax, very large amount.

Tag No. 21.—Canadian Creamery, salted. Made Dec. 6th, 1898. Preservatives, none.

Tag No. 23.—"States" Creamery, salted. Made in Wis. Dec. 14, 1898. Preservatives, absent.

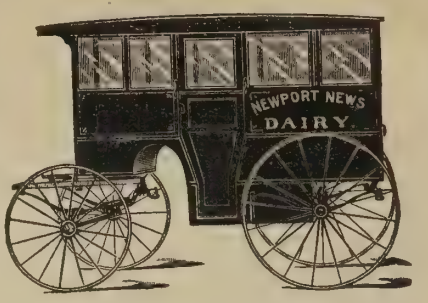
Tag No. 23a.—"States" Creamery, salted. Made in Wis. Dec. 22nd, 1898. Borax, small amount.

Tag. No. 24.—"States" Creamery, salted. Made in Minn. Dec. 13th, 1898. Borax, moderate amount.

Tag No. 24a.—"States" Creamery, salted. Made in Minn. Dec. 21st, 1898. Preservatives, none.

From these results it would appear that it is not a hard matter to sell Canadian and American butter upon the English market without resorting to the use of questionable preservatives, that will some time or other bring our product into disrepute. That the Australians use it freely is, to my mind, no excuse. If English consumers could feel sure that American butter was free from preservatives, that were freely used by the Australian butter makers, it would certainly tend to produce a sentiment in favor of our product.

A. S. MITCHELL.



Madison, Wis.

How Best To Utilize Corn Fodder.

It is quite clear at this date that the hay crop of the West will be a short one, due to the unfavorable weather conditions last winter. There is no perceptible decrease on the whole in the number of cattle or sheep, but there appears to be a quite perceptible increase in the corn and grass states, and therefore there will be more than ordinary need for the forage of the corn fields during the coming winter. Every acre of good corn has standing on it the equivalent of the feeding value of from three-fourths to a ton of hay, and the public welfare as well as that of the owner, requires that it should be made use of. How to do it at the minimum expense in cash and labor is one of the serious problems on the Western farm.

No rule of universal application can be laid down on account of the extreme diversity

The World Cannot Show Its Equal

In STYLE, CONVENIENCE and DURABILITY.

Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairyman at bed rock prices. For description and price address,

THE NATIONAL WAGON CO.,
Chillicothe, Ohio.

The YOUNG AERATOR And Cooler

Needs no water or ice, removes all odors and gasses. Warranted to keep milk sweet from 6 to 12 hours longer than any machine on the market or money refunded. Circulars free.

has now to be marketed. The easiest way to get it there is in the form of bales. THE BEST MACHINE to bale with is an

"ELI" BALING PRESS.

46-in. Feed Opening.

It makes the most compact, even-sized bales. You can get more hay in a car—cheaper freight. 88 Styles and Sizes—Horse or Steam Power. Made entirely of steel. It is light, strong and durable. Better send at once for our free illustrated catalogue.

COLLINS PLOW CO., 1155 Hampshire St., QUINCY, ILL.

of conditions on different farms. The problem of putting the corn in shock has been settled at last by the improved corn binders. There is but a few cents an acre difference between the cost of putting corn in shock and husking it out of the shock. The introduction of the corn binder has cheapened the cost of putting in shock, while the scarcity and the higher price of labor on the farm, has increased the cost of husking so that now it is an open question with some farmers, who have large numbers of hogs, whether they had better fence off part of the field and hog it down, instead of either husking or cutting it up. Where a man has forty acres of corn to cut up or where two or three neighbors have forty or over, we have not the slightest hesitation in saying that they had better purchase a corn binder. The difficulty comes in as to how to handle the corn after it is cut up. Husking corn out of the shock is entirely out of the question, for two reasons: One, the increased price of labor, and the other the damage done to the fodder by exposing the inside of the shock to the weather, to say nothing about the trouble of handling it afterwards. Where a man had to feed his corn and fodder separate, the shredder will soon be indispensable, if not now.

We do not advise every farmer to get one. He may not have enough corn to justify, or he may be feeding cattle and growing corn not for the grain, but for the cattle feed, and where he has fat cattle, stock cattle and sheep, to have a chance in turn at the fodder, we do not believe the savings would be sufficient to pay for the shredding. Few farmers, however, are thus situated, and the shrewd ones that are thus situated plant corn thick with the idea of feeding it, and aim to secure the greatest total value both of corn and fodder. The majority of farmers do not feed cattle, and hence are compelled when their corn is cut up to thrash and, shred it, so as to secure corn for the market, or for other feeding purposes, and the fodder for forage. This is particularly valuable where dairying is a specialty on the farm and where silos have not yet come into use. We believe for the small farmer who is a special dairyman, the silo is the best solution of the problem, but for the farm where dairying is but incidental, and the farmer needs a large amount of roughage to carry through stock cattle or sheep; then the shredder furnishes the best solution that has been offered up to date. Our immediate object is not to discuss the merits of either binders or shredders, but to set the farmer to thinking as to how he can get more than half as much feeding value in addition to the corn, as he usually gets off the meadow. This would be essential as the country becomes old. Our farmers are not growing nearly as much stock as they should, and by utilizing the corn fodder we can keep about one-third more cattle and other stock per quarter section than we can by wasting almost one-half of the feeding value furnished by the corn field.

Farmers have shrunk from this because of the great and unwelcome labor attached to handling corn fodder, and only utilize it in case of necessity. The binder and shredder have practically done away with the drudgery in handling corn fodder, and it is time for farmers to wake up and see that it is no longer necessary for them to have their shirt sleeves torn to pieces and their arms and faces scratched with corn blades in order to get that other half of the value of the corn fields. We speak of this from our own experience. We had seventy acres of corn fodder on our farms last year and almost as much the year before, and the hay crop with us has become a minor consideration. If you are feeding cattle and have stock cattle and sheep to follow, as we had, we believe the binder with thick planting is the solution. Where stock cattle or dairy cattle are kept, where the farmer is not feeding, but keeping stock cattle, sheep and dairy cattle, then the binder and shredder will go a good way toward making him right and happy. It is not necessary for every man to have a shredder. One shredder will do for a neighborhood and will do very much to rob farm life of its drudgery, when properly used.—*Wallace's Farmer.*

Separated Milk For Calves.

It has been estimated that every pound of butter, which is made, implies the production of about three pounds of buttermilk and from fifteen to twenty pounds of skimmed or separated milk. It may be also mentioned that every pound of cheese produces about nine pounds of whey. As regards skimmed milk, which alone will be considered, it is of course well known that its contents of butter fat vary according to the method by which the cream has been extracted. Theoretically, the liquid should contain no butter fat at all, but it is needless to say that the most completely skimmed milk, which is obtained in ordinary practice, does not reach this absolute degree of purity. Nevertheless, the butter fat content may be as small as one-hundredth of 1 per cent. Many interesting and authoritative tests have been made on this subject. In Germany, 171 trials, gave some years ago, an average of one-quarter of 1 per cent., but the improvement in the manufacture of separators has been so great that, according to Professor Wing, a centrifugal machine is not considered to be doing perfect work when it leaves more than a tenth of 1 per cent of fat in the separated milk, which contains from 8.75 to 9.5 per cent of non-fatty solids; or, in other words, 100 lbs. of the liquid contain from 9 lbs. to 10 lbs. of food material, and 90 lbs. to 91 lbs. of water. This material, which is available in such enormous quantities, is generally regarded in an unfavorable light as human food, but that is because it is commonly compared with whole milk. If it be regarded as a partial substitute for animal food, it is found to be much cheaper and to have several other advantages. Skimmed milk is often substituted for water in the preparation of various dishes, and when used in making bread it is found that the saving of flour is more than sufficient to pay for the cost of the milk; and the loaf which is produced has, moreover, a greater food value.

The profitable use of skimmed milk fed to domestic animals is well known. The results of numerous experiments, which have been made in this connection, tend to show that the liquid gives the best returns when fed to very young subjects. With this exception it is most profitable when, instead of being used alone, it is fed in combination with other foods to animals making rapid growth, in as much as it is highly nitrogenous, and when it is combined with carbonaceous material the nutritive ratio is broadened and a less "narrow" or less concentrated ration is made. It has, for instance, been recorded by the Ontario Experiment Station, after twenty years' careful work, that a young beast fed on skimmed milk, with adjuncts, may be made to weigh almost as much when one year old as a similar animal fed on whole milk with adjuncts of a similar character. The substances which are thus used in combination with the liquid are various and numerous. Skimmed milk and linseed meal, for instance, have been reported by reliable authorities to be a good substitute for whole milk in feeding calves; whereas oil-meal is found to be too nitrogenous, except for very young calves; oatmeal and maize meal giving a better-balanced ration for animals above a month old. In some parts of Germany the milk is mixed with meal or bran, and fed to milch cows in the form of a paste. The Swedish method of this character has already been referred to in these columns. The milk is heated to 160° F., and then cooled to 100° F., and rennet is subsequently added, chaff or finely-cut straw being thoroughly mixed with the liquid as it thickens. The mass is allowed to stand for three hours, and the liquid portion is drawn off and poured over the mixture in order to be absorbed to the greatest possible extent. The mass is then left to ferment for about forty-eight hours, and when fed at the rate of a gallon a day, which is said to be equivalent to four lbs. of concentrated grain food, it is reported to give satisfactory results.

The addition of starch to skimmed milk has been tried in Holland, with satisfactory results, for feeding calves. The starch was cooked to a paste in the skimmed milk, and 94 per cent of the starch was digested. A French investigator, M. André Gouin, has also, for a number of years, watched the effect of this food, which should, in his opinion, be prepared by cooking potato starch, over a slow fire, to a smooth paste with half the milk to be used; the mass being stirred to prevent the formation of "lumps." The mixture is then added to the remainder of the milk, which sufficiently cools the food so that it can be fed at once. The quantity of starch employed is one and three-fourth ounces to every quart of milk, and calves are reported to take to the ration as naturally as if it were whole milk. The young animals keep up their appetite and their condition, and the meat does not appear to be affected in any way. The rearing of calves on this food-stuff is regarded as a much more profitable way of using skimmed milk than by feeding it to pigs, and it is, in any case, of importance as an additional outlet for this dairy by-product.

The object of the addition to the skimmed milk of the various substances mentioned above is to supply to the animal, in the form of carbohydrates, the source of energy which is removed with the fat from the whole milk; the protein which the body requires for its growth and maintenance remaining available in the skimmed milk.—*Dairy World*, England.

Pure Bloods and Crosses.

Discussing pure blood and crosses in Farmers' Bulletin No. 100, issued by the United States Department of Agriculture, S. M. Tracy, M. S., says:

"In general, good pure-blood animals of any preferred breed will be found more profitable than either crosses or grades, though a poor specimen of a pure-blood animal is no better than any other poor animal. The fact that an animal has a long pedigree and is registered in a herd-book does not in itself make the animal desirable as a breeder or profitable as a feeder. A desirable breeding animal must not only have the prepotency developed by generations of breeding to a certain definite standard, but must also have the form and characters of that standard in a sufficient degree so that it is itself a good specimen of the breed. Hogs are used for nothing except for the making of pork. The pure bloods have been bred for many generations for that sole purpose The best animals, those which had the ability to make a pound of meat from the least food in the shortest time, in each generation have been selected as breeders, while inferior ones have been rejected. In this way the natural tendency of the pure-blood animals of to-day has become so fixed by generations of selections that they make a rapid growth from a small amount of food. The "scrub," on the other hand, has been bred for the development of an animal which would, to a large extent, care for itself, while quick growth, good form and fattening have been neglected, and the animal is to-day but little different from his wild ancestor. It has been literally "root hog or die," and the rooting form has been developed at the expense of the hams and side meat. When fed with an equal amount of food, the pure-blood will weigh fully twice as much as the native hog at six months or more, and when slaughtered will lose only 20 to 25 per cent of its live weight, while the native will not ordinarily dress more than two-thirds of its live weight. As the pure blood will make more meat from the same amount of food and in less time than the scrub, it is the better animal.

It is a very prevalent idea that crosses make better animals than pure-blood. It is argued that, as Berkshires and Poland-Chinas are each good, a cross will possess the special good quality of both, and so will be better than either. The crossing of two pure-blood animals of different breeds often gives pigs which are fine animals, have good forms and will mature quickly and satisfactorily. When a litter of pigs is to be raised exclusively for slaughter, such crossing is not objectionable, and many careful hog raisers think it the better practice; but the pigs from such crosses, however good they may be, are of little value as breeders. The pure-blood ancestors on both sides have been developed toward definite ideals. In the first cross there seems to be a blending of the types, and the results are often very satisfactory, but the offspring of these crosses are almost sure to show all the weakness and defects of both lines or ancestors as well as many of their own. Breeding from crosses, even though the individual animals may be of good quality, is rarely satisfactory or profitable.

Results from Alfalfa.

The chemical department of the Kansas experiment station has just completed the analyses upon one of a series of digestion experiments with alfalfa. In this experiment hay was used which was cut when in full bloom, and was fed to a 3-year-old grade Hereford steer. The results of the analyses show that the air-dry hay contained digestible nutrients as follows:

Crude protein, 10.43 per cent (consisting of albuminoids, 7.86 per cent, amids, 2.57 per cent;) fat 69 per cent; crude fiber, 15.99 per cent; carbohydrates, 28.18 per cent. The total digestible nutrients, 55.29 per cent. Let us compare the last figures with those representing these total digestible nutrients contained in some of our most common feeds used for dry roughage.

Millet contains 57.6 per cent; oat hay, 52.2 per cent; orchard grass hay, 48.2 per cent; timothy hay, 48 per cent; prairie hay, 46.7 per cent; sorghum hay, 44.2 per cent; red clover hay, 43.9 per cent; oat straw, 43.9 per cent; wheat straw, 39.2 per cent, and corn fodder, 35.8 per cent.

We find that only one of the ten feeds named is equal to, or exceeds, alfalfa in its total content of digestible nutrients, while the larger part of them are far below it. This is not a fair measure of its feeding value, however, unless we also take into account the composition of these nutrients. As a rule, it costs much more to produce feeds rich in protein than it does those rich in carbohydrates, and consequently, of the two feeds containing an equal amount of digestible nutrients, the one containing the most protein is the most valuable. Comparing alfalfa in this respect with the above named feeds, we find that it ranks far ahead of the richest of them. One hundred pounds of alfalfa hay contains 11.3 pounds more digestible matter than the same amount of red clover hay and 1½ times as much protein. It contains only 2.3 pounds less of total digestible nutrients than the same amount of millet hay, and almost 2½ times as much digestible protein. It contains 2½ times as much digestible protein as oat hay; 3 times as much as prairie hay; 4 times as much as sorghum hay; 5 times as much as corn fodder; 6½ times as much as oat straw, and 13 times as much as wheat straw.

In feeding value, alfalfa hay not only ranks high above all other feeds used for roughage, but it is well up among the more concentrated feeds. One hundred pounds of it contains 3.3 pounds more of total digestible nutrients than wheat bran, and almost as much protein. It is richer in digestible protein than wheat, corn, oats, rye, barley, kafir corn or sorghum seed.

Its digestible nutrients have a nutritive ratio of 1 to 4.4. There are only a few feeds, such as wheat bran, linseed meal, cottonseed meal and soy beans that furnish as narrow a nutritive ratio as this.

Alfalfa hay, therefore, is an ideal feed to use in balanced rations, and is especially valuable to combine with corn as a ration for fattening steers, since it furnishes all the roughage necessary and is also a cheap source of protein. It is an ideal dairy feed, furnishing almost the exact nutritive ratio required for the highest yields of milk. Its value as a feed for hogs has been shown in results previously published by this station. —*California Rural Spirit.*

Tainted Milk.

After a dry season, such as we had this spring, we always expect to hear complaints about bitter flavor in milk and butter. These troubles are not so frequent as they were twenty-five years ago, because the causes that produce them are better known, and more generally avoided, but there are some yet who do not understand them, and allow the cause to go uncorrected until the butter is so bad that no one can eat it.

When the pastures are as dry as now, the grass dries up while the weeds remain green, especially that very bitter weed known as the Roman wormwood, common in nearly all old fields. That weed seems to flourish best when all other vegetation is at a standstill from lack of moisture. The cows usually avoid it, or eat but small quantities of it when mixed with grass, but when hunger drives them to it, they will eat it and it will give its flavor to the milk and cream, and we do not doubt but if the animal was killed, after a week or two of such diet, the same flavor would be found in the flesh.

There are other weeds, not quite as bitter which are sometimes eaten, and we have seen the leaves of birches and other trees or shrubs eaten by cows in scanty pastures, any of which would be likely to flavor the milk unpleasantly. We need not seek far for a remedy. Remove the cows from the pastures where weeds are more abundant than grass, and give them fodder, either in a better field or at the barn, even cutting clover and corn fodder for them until they are not tempted to eat weeds.

This taint from weeds will usually be noticed as quickly in milk as in cream or butter, but there is another bitter flavor which is often not detected until the butter has become a few days or a week old, but develops rapidly after that time. This also is most frequent in a dry season, though we have been asked to account for it nearly all seasons of the year. In most cases we have traced it directly to the use of impure or stagnant water.

When brooks, ponds or wells grow low, impurities existing in it become much more powerful than when they are diluted, or when the swift running streams carry them away. Carefully watch the drinking places of the cows, and see that they do not have to drink out of stagnant puddles, nor to wade in and stir up decayed and decaying vegetable matter, and other deposits that accumulate at the bottom of slow running water.

We have in some cases been obliged to think the trouble arose from the ill health of the animal, and probably a diseased liver, but in one case at least, after deciding that the water supply was pure, being from a good well, we found that one cow did not drink with the rest when there was a dirty puddle in the barnyard, filled with liquid manure. It was a case of depraved appetite, possibly the result of some disease. When her milk was not used with that of the other cows the butter had a good flavor again, and kept it. And after she was prevented from drinking at the puddle, and had been well physicked out with Epsom salts, and then given salt to make her relish good pure water, she soon became all right again.—*American Cultivator.*

Improvement of the Soil the First Element of Successful Dairying.

[Paper read before the New Hampshire Dairymen's Association by GEO. T. POWELL.]

Never in the history of our country has land in New England, with its improvements, reached so low a point in value as at the present. Never has it been more difficult for a farmer to change his business, or to sell his farm than now. Many that once considered investment in land so desirable and safe, now draw away from it. The highest rates of interest are exacted from farmers, because of the greater risk incurred, hence needed improvements are not made and steady depreciation goes on.

Now what determines the value of land, or of any other property? It is its earning power, its ability to return a profit upon the investment made in it. There are certain causes that have been operating to lower the value of agricultural products. Our public lands have been too rapidly turned into production; many acres a century, at least, before they were needed. Transportation has been most wonderfully developed to meet this greatly increased production, and from these causes the farms of New England, with their improvements, have been reduced in value to the level of the cheap and unimproved lands of our public domain.

But the important question that is before this association to-day is the condition of the soil upon the farms here represented. How, as dairymen, can you increase the earning power of your farms? The older farmers of this audience have been successful in their day; they have been the great force that has built up this New England thrift and enterprise. They have contributed to the upbuilding of the great manufacturing industries of our country by their industrious and educated sons, and while the best brains have gone out from these New England farms, we want some of the best to remain on these farms to give them the better development they so much need.

Farmers, your discouraged sons can never repeat your earlier successes in the same manner. You were successful, not so much from superior management and judgment, as from the fact that your efforts were blessed by a highly productive soil. You have taken out the cream of the wealth that was in the soil, and for your sons to continue to abstract wealth from this same soil, involves them in entirely different problems. They cannot go on in the same methods and succeed; they cannot even afford to inherit your farms and pursue your methods, for it would only be a question of time when they would be practically disinherited by the soil itself, which now refuses to be longer mismanaged.

The general impression prevails that the farms of New England are exhausted of fertility and are worn out, hence unprofitable for agricultural purposes. Such is neither the truth nor the fact. There is not an acre of exhausted soil in New Hampshire, and when much of the rich alluvial soil of the great West has undergone the same abuse, an experience that is going on more rapidly than in the East, and much of this western land is abandoned, New England farms will be found still feeding millions of dependent consumers. [Applause]. I have faith in a greater development and improvement in the land of the East, than we have ever yet known. Every other great industry has been leading in an unusual development. From this time on agriculture is to be a new field, and in this there is great promise and hopefulness. Now let us go to the direct consideration of this new development, and the promises it holds out.

The improvement of the soil is the first factor; from it all of our hopes and results must come, and let us now consider its most practical accomplishment. The foundation for soil improvement must begin with tillage. So abundantly is our soil supplied with plant food that the Creator has made it impossible for many generations of men to exhaust it. After upwards of two centuries of great production, the character of our soil has been changed, and we have now to put far more labor upon it. If I were to ask you what is the object of tillage, probably a large majority would answer, to keep down the weeds. While that is one of the purposes of tillage, it is by no means the first. We must return thanks to the Lord for the persistence of weeds, for without them to force many farmers to their fields with cultivation, many crops would prove total failures for want of working the soil, so that weeds are among our real blessings.

We do not give sufficient consideration to our plows, to their construction with reference to the more thorough manipulation of the soil. We must not buy plows on the recommendation alone that they are easy of draught. In a trial of two new plows on my farm, one was claimed to be very much lighter draught than the other. They were both put to work, and my men chose the easier running plow. On examination of the soil a decided difference was observed; one plow would cut and turn its slice smoothly, and with the least possible resistance. The other turned its furrow well, but in doing so its action on the soil was entirely different. It twisted and broke and fairly ground the soil, leaving it apparently in a rougher condition. This was by far the most valuable plow, for while it was harder work for the team and the man, it accomplished what we want of a plow, the more thorough breaking of the soil, for in so doing it is liberating more of the plant food that is still so abundant in the soil. We need to study the construction of mold-boards and land sides to know if they will handle the soil as it must be done to-day. The jointer should always be used. It helps in the more thorough reduction of the soil, which is the real object in plowing. The next process of tillage is the use of harrows and cultivators. These are of different kinds, but the object of their use is the same, the greater refining of the soil, that its plant food may be made more easily available.

One reason why it is necessary to give more attention to the thorough tillage, is the mechanical condition of the soil. In the many years of production of cereals, we have very largely worn out and used up the vegetable, organic or humus matter in the soil, and this has changed its texture. It seems much of the time to be in a too hard, compact condition, not holding or retaining moisture, failing quickly to carry crops in times of drouth. Tillage, then, has a further object in putting the soil in a much finer tilth, that it may hold or retain longer the moisture so necessary to growing crops. We cannot depend upon the rain fall to carry our crops through during their period of growth. We have to depend on that more largely that is stored in the earth, and now we must apply tillage to the proper control of the water supply that is generally abundant in the soil.

On all cultivated crops, then, we must plow the land early in the spring, or if already plowed, begin to till it early, for as the warm days of spring and summer come along, the water movement toward the surface of the soil becomes more active, and the loss by evaporation grows rapidly, daily. Every day the soil lies undisturbed in the spring, the greater will be the loss of the water supply for the season, hence early tillage becomes very important. Till deep early in the season, and lighter as the hot weather approaches, and by this system we cut off the loss largely by evaporation, in sealing the surface by this fine cov ering which comes from frequent light surface tillage, and the moisture is held for the use of growing plants. This system of tillage will improve the soil, and increase the yield of crops without the aid of extra fertilizers, and it is better business practice to obtain and make use of the fertility that is under our feet first before we expend money for artificial plant food.

In this important problem of improving soil we must use other agencies that will assist tillage. For a number of years I have been working with crimson clover, and with some very marked results. I speak of crimson clover because of its peculiar fitness for the purpose I desire to accomplish. I lay down the principle that we can continue taking out crops from the soil, and after doing so leave the soil in better condition than before their production. This seems like a very strong statement to make, but I will try to give you a demonstration of the fact.

When I began farming, I started on a farm that for several generations had been producing wheat, and other cereals, hay and potatoes. The system was changed, and the farm was covered with orchards and vineyards. I soon discovered the soil was not equal to producing regular annual crops of fruit of fine quality, and a much more extensive plan of tillage was begun. This was followed by plowing in buckwheat and rye, and while these gave favorable results in changing the mechanical condition of the soil, they did not enrich it materially, and

out of great cows and by the best sires, for sale at Dairymen's Prices. Also large English Berkshires, imported and native bred. Apply to GEO. F. WESTON, Supt., Biltmore, N. C.

MILLER & SIBLEYS JERSEYS.

Ida's Rioter of St. L. leads all other bulls in average for 29 tested daughters, viz.: over 20 lbs. of butter apiece in a week. All full weekly tests, by eight different owners. He weighed 1,760 lbs. His dam's record, 455½ lbs. milk, 30 lbs. 2½ oz. butter (official test) in 7 days. FOR SALE—Grandsons and granddaughters of Ida's Rioter of St. L.; also cows in calf to his sons.

224 First Prizes and Sweepstakes at 22 State Fairs or great Expositions. 224

Big cows, Sound cows, Heavy Milkers and Great Butter Makers. Our Adelaide of St. Lambert gave 82¾ lbs. milk in one day, 2005¼ lbs. in one month, the world's Jersey record. Many other championship records. No catalogue. Special literature sent if this paper is mentioned. No animal sold for less than $100. Lowest price for quality. Every animal tuberculin tested before sale, if desired. Also for sale, Children's Ponies and Imported Shropshire Sheep. Franklin, Venango Co., Pa.

The Lone Tree Jerseys

THE largest collection of high testing cattle in the West, including home-bred and Island cows. Show and Breeding Stock always in supply. Especial attention given to furnishing foundation stock for pedigreed herds. A superb lot of young bulls and heifers now in special offer, including some sure prize winners.

Introduce Fresh Island Blood Into Your Herd.

SIRES IN SERVICE:—The prize winning IDA'S RIOTER OF ST. LAMBERT 10th, the champion CATONO KHEDIVE, the champion CZAR COOMASSIE, and IMP. GOLDEN BAR, inbred through his sire, Aristocrat, and his dam, Imp. Sandgate, to Golden Lad, the greatest bull on the Island of Jersey.

Write for what you want. Visitors always welcome. JOHN E. ROBBINS, Greensburg, Ind.

Butter Bred Bull Calf, 10 MOS. OLD, a Little White.

Very handsome . . . Send For Pedigree. $50. J. P. BRADBURY Pomeroy, Ohio.

crimson clover was tried, and has now been used for five years. Crimson clover was chosen for the reason that it is an annual plant, and grows more rapidly in a given time; also for the reason that it grows better in the cool autumn months, and can be sown on all cultivated crops after the cultivation ceases. On a dairy farm it can be sown in corn at the last cultivation in July, using ten to twelve pounds of seed per acre, covering the seed very lightly the last time the corn is cultivated. It can be sown in potatoes in the same manner; it can be sown in buckwheat; and I have also sown it in early spring in oats successfully, and plowed it in for rye in the autumn. There have been many failures with this plant and it has been condemned; there have also, for several years, been many failures with red clover. We want to understand clearly the object for which we use crimson clover, which is only for the improvement of the soil. It is not for pasturage, neither for hay. We want to obtain the largest possible growth of this plant from July to December, and during this time it is capable of doing us great good.

I discovered after two or three years use of this clover a marked improvement going on in my soil, also noticed that in seasons of long drouths large crops of fruit and of corn were carried through much more successfully. The clover grew well during the autumn, and was plowed in early the following spring.

While conducting schools of agriculture in my state for farmers, under the auspices of "The Committee for the Promotion of Agriculture," and later for Cornell University, a chemist from Cornell assisting, desired to determine the actual extent of improvement that had been made in the soil by this clover treatment. It has long been claimed that clover can add fertility to the soil in the form of nitrogen taken from the atmosphere, and while it has been proven in the laboratory of the chemist, no one has attempted to prove what could be done on a large scale with an entire farm. Samples of soil were taken from an orchard where the clover had been plowed in for three years, and sent to the chemist at Cornell to be analyzed. A sample was also sent from the orchard where no clover had been used. The conditions were entirely the same, and had been for several years previous. The figures on the chart here shown give some very interesting results·

CRIMSON CLOVER AS A GREEN MANURE.

ANALYSIS OF SOILS.

	Three crops clover.	*No clover.*
Water	15.00 per cent	8.75 per cent.
Nitrogen	.21 " "	.12 " "
Humus	2.94 " "	1.91 " "
Phos. acid (available)	.015 " "	.008 " "
Water	6.25 " "	equals 46.875 tons.
Nitrogen	.09 " "	" 1,350 lbs,
Phos. acid	.007 " "	" 105 lbs.

Here the work of the scientific man, which is positive and accurate (for there is no guess work in scientific investigations), corroborates the practical results that have been obtained over a large acreage. We have been successful in growing this clover in many ways. This sample of the plant was taken out of corn ground only a week ago, and its stalks will measure five to seven inches in length. We have it of equally good growth in potato ground, in orchards, vineyards, small fruit plantations, also a good stand where oats and buckwheat have been grown, covering eighty acres. The past season, while potatoes have been a general failure, we have succeeded in growing an excellent crop where a heavy growth of clover was plowed in, on corn ground.

The figures in this analysis show some very valuable and interesting facts. The difference in moisture in these two soils makes nearly forty-seven tons more of water in the clover field per acre, and this is made possible by the greater amount of humus which the plant has added in three years, nearly double that found in the soil where no clover has been used. This readily explains why we have carried some large crops through long drouths without serious injury to them. The figures on nitrogen are the most significant. The difference in nitrogen found in favor of the clover treated soil for three years makes 1,350 pounds per acre, and figuring its cost at the lowest price it can be bought for in a wholesale way, at fifteen cents per pound, it has added $202.50 in value of this costly plant food per acre. It was also found that there was a larger amount of available phosphoric acid in the clover treated soil. The potash results have not yet been determined.

The conditions in New Hampshire may be somewhat different from New York, yet if you can get a fairly good growth during the autumn, it will be of value to your dairy interests. I believe there are far greater possibilities in a higher development of New England farms than anything we have known. The drift of population has been to the West, but the alluvial soils of the West will stand no such long period of production as yours. Already, the wheat and corn fields have gone down over fifty per cent in many sections in less than thirty years, and when some of this apparently inexhaustible western land shall have been abandoned, you will see the tide setting back to the East. Your New Hampshire farms will again be sought after, and New England will continue to feed millions for time to come as she always has. [Applause.]

It is for the dairymen of your state to intelligently study this question of the improvement of your soil, which means improvement along the entire line of your agriculture, of your grasses, of your cereals, of your herds and of their products, and by no means least in importance, farmers.

Separator Questions.

ED. HOARD'S DAIRYMAN;—In your issue of July 28, I have been very much interested in an article on separators, by Mark Sprague. I am the owner of a separator, and although the mechanical running of the machine seems to be all that one could wish, I must confess that the scientific features that present themselves at different times are calculated to stimulate thought and investigation.

We wish to submit to Mr. Sprague, or some one else of your choosing, a few questions that we should like to have explained.

1st. Is it generally understood that a morning's milking will produce more cream per gallon, than that of a night's milking? It is almost universally so with us, with cream of the same quality. Cows run in quite a large pasture during the day, and are confined in a small yard at night. Would this make any difference?

2nd. We had supposed that a separator once adjusted as to the quality of the cream, would always produce the same article; whether more or less per gallon, the quality would be the same. This is usually the case with us, but not always. On a few occasions we have been startled by the appearance of a large flow of cream from the machine, much thiner than usual, without having changed the adjustment of the parts in any way. Is this caused by any difference in the speed of running, the flow of milk into the bowl, or what? The flow of milk into the bowl is regulated by a float, as we suppose all are, and I do not see how it could be changed by the flow from the tank.

How is it possible to change the flow of milk into a bowl, where a float is used, and the capacity of the float cover already established?

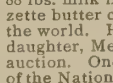
We believe that separator builders have their business down to a very nice point, mechanically, but we are of the opinion, that there are many scientific results yet to be established, that we do not see mentioned in their catalogues.

We did not know until recently that a cow would give richer milk in the morning than she would at night, but it would be hard to make us think otherwise now.

A few explanations in regard to the above will be greatly appreciated.

Annapolis, Md. H. L. COMBS.

This is a case where experience is worth more than theory. Will some of our readers, who have had experience in the above line, help us out?



"The Man With the Hoe."

Edwin Markham's unfortunate poem, "The Man With the Hoe," has brought more or less misplaced odium on that useful implement. Newspapers are referring to the hoe as though it were a type of degradation, rather than a fitting emblem of the dignity of labor. And some of the preachers have fallen into the same error. The Rev. A. B. Wilson, of San Francisco, the other day, said in the course of a sermon, that "drink puts a hoe in a man's hand." He meant that the tendency of drink is to make or keep a man a laborer—a toiler for hire; to destroy thrift and industry. But his expression was not well chosen, save as an apt reference to Markham's poem. The fact is, that there are thousands of fellows writing foolish verses, who would be much better employed if they were hoeing potatoes or corn. The great trouble with this country is, that there is not enough hoeing. If drink would put a hoe into the hands of the thousands of genteel loafers and bilks who crowd the large towns and cities, it would be a good thing to leave plenty of free whiskey on tap.

So far as any application to labor in this country is concerned, Markham's poem is mere sentimental rubbish. It is true, that he uses the word hoe simply as a symbol of peasant labor, as pictured in the famous painting of Millais. But, unhappily, his verses are having the effect of increasing in this country the evil tendency to crowd the cities at the expense of rural pursuits. In America the young man with the hoe, and with the will, and muscle, and horse sense to use it properly, has a better prospect in life, than the average young cigarette smoker in the cities, who undertakes to eke out a living with the pen. We have too many poor poets and bad writers, and not enough good farmers. Let us honor the hoe and those who wield it in the hope and prospect, that all Americans may have, of thereby securing a good home in the country.—*Pacific Bee.*

GUERNSEYS FOR SALE. The increase of my herd is a few young things of both sexes, from one to eighteen months old. Prices corresponding to age and quality. **F. W. TRATT, Whitewater, Wis.**

GUERNSEY Cattle—SHETLAND PONIES.—Old Homestead Herd was Champion at O., Ill. and Ind. State Fairs, 1898, winning against well-known O., Pa., and N. J. Guernsey show herds. Over twice as much prize money as all competitors combined at above fairs. No better collection in America. Breeding Stock for Sale. Inspection invited. L. V. AXTELL, Perry, Lake Co., O.

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

SHADY NOOK HERD Holstein-Friesians Choice Chester-White Pigs 2 to 3 months old, both sexes, for sale. W. R. GATES, Ripley, Jefferson Co., Wis.

TIRANNIA

The third highest butter cow in Holstein history is owned with three of her daughters at **Valley Mead Farm.** Tirannia's butter record is 36 lbs. 11 oz. in seven days, 91 lbs. milk in one day. She is the winner of the Great butter prize of 1889, of a Gold Medal and $100 for making the largest fair ground test in the world, viz: 3 lbs. 2 oz. in one day. Also was sweepstakes public tested cow of the breed of 1891. H. F. Register says: "Few if any better or more beautiful cows ever lived than Tirannia, and her performance as a butter cow is in keeping with her beauty almost unapproachable." She once sold for $1500. **Valley Mead Farm,** Monticello, Wis.

A MILK and BUTTER Holstein.

Pietertje Sir Tirannia Royal.

Dropped Aug. 4, 1898. A grand individual now ready for service. In his veins flows the blood of the greatest cows of the breed: Pietertje 2nd, 112 lbs. milk in 1 day, 30,318 lbs. in 1 year. Oude Empress, 114 lbs. milk in 1 day. Mechtchilde, 112 lbs. 1 day; sold for $2,500.00. Empress, 109 lbs. milk in 1 day. Mink, 96 lbs. milk in 1 day. Pietertje, 93 lbs. milk in 1 day. De Gonde, 91½ lbs. milk in 1 day; a prize cow at the Paris Exposition. Tirannia, 91 lbs. milk in 1 day; winner of the National Butter Test, in a ring of 73 cows from 12 states. Castine, winner of the $1,000 butter prize at the Inter-State Butter Test, at Buffalo; also winner of the Ohio state butter test. Mercedes 88 lbs. milk in 1 day; winner of the Breeder's Gazette butter challenge cup, open to all herds in the world. Her son, Jacob, sold for $5,000. Her daughter, Mercedes 3d, sold for $4,200 at public auction. Ondine, 90½ lbs. milk in 1 day; winner of the National Butter Test at Rotterdam, Holland. Also a large list of other noted animals. **Price, $75.00.** If you want him, write at once.

Quality of Hay.—A Dairy Lesson.—Hydraulic Separators.—Raising Horses.

ED. HOARD'S DAIRYMAN:—Some farmers have twenty acres of grass uncut; others have a good crop of clover aftermath just beginning to blossom. Their first crop was in the barns before July 4th, with all its feeding value in it. The grass now uncut is comparatively worthless, its starch and sugar is gone, having been replaced with wood fiber and gum, while the nitrogen and phosphoric acid have found a convenient hiding place in the dry seed.

Yesterday, I saw a field of twenty acres—possibly more—of "river flat" that, July 1st, would have produced not less than two tons of fairly good timothy per acre, but was so dry that there appeared only a bottom growth of, say, six inches of green matter, while the original crop was disputing with a fine growth of wild carrots—gone to seed, too—for supremacy. It was not worth the cost of cutting and curing, for feeding purposes.

Another small farmer has six scrub cows, part of them Jersey grades, which give 4.5% milk, together with a half dozen sheep, busily tramping over six acres of dry daisy pasture, fighting flies and searching for rations. Their owner had about a dozen acres of timothy, good for one ton each, July 1st, some of which is yet in windrows, and beside it, three acres of corn not yet tasseled, that has not been visited by either hoe or cultivator.

Those cows ran in the same pasture last year, in company with the same sheep, and luxuriated on the same diet of daisies.

The owner peddled their milk at four cents a quart, but did not realize $30 each from it, while every pound of hay, corn stalks and oat straw grown on twenty acres—minus that fed to a pair of horses and the six sheep—went the way of all dry timothy which is not burned. How much spot cash is there in such farming?

Last winter one could see the seat of his mowing machine, the wheels of his horse rake and the handles of his cultivator sunning themselves above the snow in the field, where they were last used. He had left them in convenient places to hitch to this summer, which he did, the cultivator excepted.

Coax that man to subscribe for HOARD'S DAIRYMAN? Guess not, nor for any other high-class agricultural paper. He knows too much now, being of the class mentioned by Dr. Jordan, at Gouverneur last winter, as "too cussed smart."

A near neighbor of this man has a high grade — seven-eighths — Jersey cow, eight years old, that has been kept on the product of less than two acres of land, the last three years, during which time she has not been dry.

During the year beginning July 7th, 1898, and ending June 25th last, 400 pounds of butter were made, besides supplying a family of three with milk and cream, and during six weeks, while her owner was ill, from one to two quarts of milk per day to a neighbor for milking her night and morning. The butter sold averaged 19 cents per pound, all going to regular customers, who, like Oliver Twist, clamored for more. The calf sold, at three days of age, for $5, thus giving a total yield of $90.50 for the year.

The milk was creamed in small open pans, without ice, and no pains taken to properly mix and ripen the cream, which was churned in a dash churn.

I frequently saw the buttermilk, which was rich in unchurned cream, and called the attention of the lady to it, but she said she could not do differently, situated as she was. Had that milk been passed through a separator and the cream properly ripened and churned, that cow would have produced more than 500 pounds of butter of the very best quality during the year, and with proper, judicious feeding, her revenue could easily have been brought up to the $100 notch, and at but little extra expense.

Her milk was allowed to sour and was then given to a pig, from June 20th to July 20th, during which time she was milked three times some days. She is now making about 14 pounds of butter in seven days and has nothing but pasture—about an acre—and a quart of bran twice a day. Which of the two dairies would you invest in?

Not long since I noticed a statement going the rounds of the agricultural press—the DAIRYMAN included—in which it was stated that 300 farmers near Carthage, this state, had been threatened with prosecution in the supreme court for using a certain make of aquatic cream separator—so-called—unless they put up a royalty fee.

No doubt but there are a few of these frauds in use in the vicinity of Carthage, but to say they number 300, is putting it altogether too strong, because, in the first place, there are not one-fourth that number of dairymen near Carthage, and in the second place, there are milk stations all along the railroad between there and Utica, the first one being at Deer River, six miles from Carthage, and nearly every farmer thereabout, who does not draw his milk to one of these stations, patronizes one of the several cheese factories thereabout, one of which is the celebrated "Crown Brand" factory of the Cook Bros., at Denmark, eight miles from Carthage, so that there is no place for these separators "near Carthage," the farmers having no use for them.

But they are manufactured in Watertown, as well as elsewhere, and hundreds of them are being sold to the fool farmer who never attends an institute nor reads a dairy or agricultural paper of value.

I saw one of the Watertown make, at a depot, recently, billed to a farmer in a Jefferson County, Wisconsin town. Of course, they are advertised extensively in the country weeklies and Cheap-John farm papers, the only ones the victims read, and for which they are usually owing for two to six years' subscription.

But "their eyes is sot," you can't reach them; so there is no need of wasting space and cold type on them. Let them pursue "the even tenor of their ways" and give them the opportunity to buy "green goods," aquatic cream separators, lightning rods or "gold bricks;" or to invest the few surplus shekels they may chance to have accumulated, in the funds of a Chicago or other "creamery promoter" deal. Paul may plant, Apollos may water, and you may write and print reams of editorial warnings, but these men will not profit thereby, as they neither listen nor read.

Three or four years since, when the average farm horse had dropped to the lowest level in price, and when "ten shillin a dozen," was a fair average for them, the speakers at our institute urged the farmers to begin the raising of horses.

The advice was to select their best mares—those that were of good size and action, perfectly sound, and of good age—then breed them to thoroughbred sires of certain types—French coach, Cleveland bays, Hackneys, and draught stallions were recommended as best. The speakers said that the near future would bring a market for good horses, with prices that would yield a nice profit.

The prophecy was true; the time has come and with it the demand and the prices; but there are no horses, such as were recommended, which are the types wanted. Of late, buyers from the east have been in the country, searching for such horses, but have found but very few. When found, however, prices varying from $150 to $500 have been paid, and, when a pair of matched drivers has been found, that just filled the bill, still higher figures have been paid.

The average farmer, however, he with the scrub cows and scrub horses, has none to sell, but is just begining to talk about "raisin a colt or two;" and one may occasionally see an old-fashioned, county dual-purpose, no purpose stallion and driver passing along the road.

The driver, mounted on an old sulky, wearing a cap—the driver, not the sulky, with a long visor, and the stallion squealing at everything in sight. One of those drivers said to me, recently, in answer to a few questions, "Yes, my biznis is just beginnin to boom agin. Seems kinder old-fashioned, after so long a dull time. The farmers hes got to go ter rasin colts; first, because there ain't no horses scarcely in the country, and them that is, is gettin old, and must soon be replaced; then, too, prices are goin up to the profit notch."

"Yes," I said, "but the markets don't want the type of horse you are driving. They

Gluten Feed is used by nearly all successful dairymen, and has become a necessary article for any dairyman farmer who wishes to keep pace with the successful men in his line of business.

Gluten Feed increases the flow of milk, improves the quality, keeps the cattle in the best possible condition—in fact, helps you make more money out of your dairy. This is not cheap talk. We mean business. Gluten Feed is all and more than we claim for it, and, best of all, a trial proves it. Sample of Gluten Feed, Milk Talk Pamphlet, and circular illustrating the "Valve of Butter Fat in Milk," all FREE if you address

want thoroughbreds or high grades of certain form and style. For instance, draught or roadsters or saddle horses."

"Oh, well, I know there's a call now an then for a hoss or two of that kind, but they ain't many of em; and its only casionally som city dude wants em. What the farmer wants is good, hardy, good sized hosses that can plow two acres of sod a day and then do an eight mile clip, hitched to a road wagon with the wimmin folks on it, to church Sundays, or to the post office Saturday evenins."

"He don't want any of your draught nor French coach nor saddle hosses. Who rides a hoss now-a-days. See any body doin it. Guess not; casionally one sees a girl or dude or some boy ridin a pony; that's all. Everybody's got a bike. No, my friend, you don't want to talk any such nonsense. The farmers is never goin to believe you if you do, cause they know better."

"Don't know of any one bout here havin a good likely old mare or two that they want to breed, do you? If you do, tell 'em I am just opening the season, and have a hoss that will suit 'em every time." Then he drove along, whistling, "Just tell em that you saw me." C. W. JENNINGS.

Bellville, N. Y.

Summer Butter Making.

[Paper read before the Ontario Cheese and Butter Makers' Association by FRED DEAN.]

A butter maker cannot have any fixed rules for manufacturing first-class butter. Each day brings him new experiences and trials, which can only be overcome by using that which is most essential, yet too often lacking in a butter maker—common sense. We are so often irritated by the little things and mistakes in our business, that if a little of the aforesaid substance had been used, we would have fewer troubles. The main object is securing a first-class article of butter in the summer time, and the key note is "cleanliness," from the food and water given to the cow, until the butter is placed in the hands of the consumer. So much has been said and written on this point, that you really would think there was nothing more to say, but it is only by nagging away, from time to time, that perhaps, at last, our object will be accomplished, and that is by educating the farmer to co-operate in this industry, feeding his cow such food that will not taint the milk, and keep her healthy, letting her have abundance of good pure water, and not drink out of any mud hole in some corner of the pasture field, or along the side of the road.

We must show him how he can best aerate his milk, by running it over an aerator, or using a solid handled dipper to stir it thoroughly, letting the animal odors off, and have it purified by coming in contact with the atmosphere out doors; then cooling it down so that fermentation will not take place, taking into consideration that it has been strained and put into vessels that have been thoroughly washed, scalded, and steamed. If you have educated the farmer up to this point, your butter is half made, for it is this fighting filth and carelessness, on the part of the patron, that keeps summer makers continually in hot water.

The best of butter makers fail now and again to make an even quality of butter, even when they have educated the patron, and receive a first-class lot of milk. This, no doubt, is owing to the different changes and conditions of the milk and weather, and cannot be placed to the discredit of either; but we are in an age now when nothing seems too great for man or machinery to overcome, and to overcome this point we must pasteurize our milk or cream every day to get this even quality, and be able to compete with foreign countries in obtaining a high price in the Old Country market. This is what we are making preparations for during the coming season. At each of the stations a pasteurizer will be placed to pasteurize the cream only. The cream drawer will then bring it to the central station, where it will be run over the cooler to a temperature of sixty degrees. A skim milk starter is used, being made of a half can of good, pure skim milk. Pasteurize all this by heating to one hundred and sixty degrees, and let it stand for twenty minutes. Then add as much good spring water as milk, which cools it down to ninety-eight; stir it well and add one dipper full of the old starter, changed once in two weeks, by letting the skim milk stand two days without adding the ferment. Use buttermilk that day, or if your buttermilk is of an even flavor and good, use it right along.

The starter is put in the vat before the cream, so that fermentation takes place immediately. When about twenty-eight or thirty-hundredths per cent of acid is shown by the acid test, cool down quickly as possibly to forty-eight or fifty degrees, stirring it every half hour or so with a common hay rake, which has given me the best of satisfaction.

After the cream is all pumped up and strained, the pipes are thoroughly flushed with luke warm water, then steamed, followed with boiling water, pumped through them each day. The cream should be kept at churning temperature from ten to twelve hours before churning, and be well stirred before putting it into the churn, and should not show any more than six-tenths per cent of acid, or less than five-tenths per cent. If too much acid has developed, the casein coagulates firmly during the churning and breaks up into small white specks, which are incorporated in the butter, giving it a bad appearance, and when a few weeks old a very disagreeable flavor. When the cream has not sufficient acid, it lacks in flavor, will not keep so long, and a larger per cent of fat will be found in the buttermilk.

When the churn has been scalded and cooled, strain the cream through a zinc strainer, filling the churn one-half full, or a little over, revolving from fifty-five to sixty revolutions per minute, taking from thirty-five to forty-five minutes to churn at a temperature of fifty degrees.

When the cream begins to swish in the churn, it is a sign that it has broken, showing minute specks of butter. Stop the churn and add a pail of water the temperature of cream, with a handful of salt, which gives the butter a better chance to separate from the buttermilk and hardens the globules. Let the churn revolve again, until the butter shows about the size of wheat grains, when the buttermilk is drawn off, and after draining for five minutes, let the water at forty-eight degrees run through until it is clear; close the tap and fill the churn two-thirds full, revolve for half minute, and draw off water, rinsing down with same. After the butter has drained for fifteen or twenty minutes, it is shoveled into eighty-pound tubs and weighed, putting two into the worker, then sprinkling on five pounds of salt, and again adding two more tubs, finishing salting at one-half to five-eighths of an ounce to one pound of butter.

We use the National worker with an indicator, letting it work for about four minutes; then drain five minutes, and finish working it in from six to seven minutes, according to the texture, which is shown by breaking over the roller reluctantly, and when pressed by the finger gives a velvety and waxy feel. The butter is only worked once, and during the summer we never had a mottle or greasy package.

When ready for packing, the butter is put on a long table, with scales at one end, and another smaller table used for boxes, which are twelve and a quarter inches square, made of spruce, paraffined on the inside and lined with very heavy parchment paper, fifty-two inches long, and twelve and a half inches wide, two strips in each box, soaked in strong brine from twelve to fifteen hours before using.

Butter that is to be packed for future consumption should be a great deal drier than that intended for immediate use. It should also be packed solidly, so that when turned out of the box, it will not show any crevices for brine to lodge, giving it an unsightly appearance. When the box is filled put it on the scales and scrape off butter with a stick of wood, twenty inches long, having four inches grooved off each end, with a movable strip fastened with a screw, letting it raise or lower according to the amount you wish to take off, allowing one and one-half pounds for shrinkage, A weak brine is now poured over the butter to prevent molding, and the butter from sticking to the paper; fold the four ends over and put on a heavy paste of water and salt about one-quarter of an inch thick, fastening on the lid with screw nails. Put the butter in a room, the first day, with a temperature between forty-five and fifty degrees, so that it will have a chance to cool gradually before putting it into the refrigerating room, which should be at a temperature of thirty to thirty-five, and if kept for any length of time, below thirty. After the day's make is over wash all woodenware in boiling water, steam thoroughly, and give a light sprinkling of salt over everything. Scrub the floors, which should be of cement, with boiling water, and then pour a dozen or so pails of the same down each waste pipe and gutter, accompanied every two or three weeks with a solution of copperas.

Hairy or Winter Vetches.

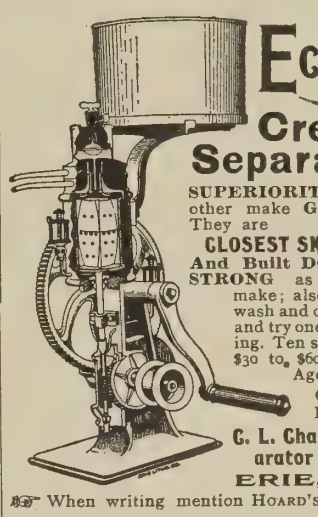
ED. HOARD'S DAIRYMAN:—In reply to inquiry of J. P. D., on page 390-91, will say: These vetches thrive upon all kinds of soil in this locality, in fact, are so hardy that stray plants exist in old sod and at the sides of roads. For soiling, sow about one and one-half bushels per acre, of a mixture of equal parts by weight of vetches and rye, using a grain drill.

We plant about Sept. 1st, having the ground well prepared. If soil is strong two crops can be cut off in time to allow growing a considerable crop of fodder corn.

J. H. NELLIS.

Montgomery Co., N. Y.

Beware of Cheapness.



BEWARE of the butter color that an agent claims to be *"just as good"* as W. R. & Co.'s Improved, but which he offers at a cheaper price.

There is not and never has been a color *"just as good."*

Why should any one be obliged to offer a color at less price if it is *"just as good."*

While cheap colors may be cheap in price, they are expensive to use.

"THE KIND THAT HAS NO MUD"

☞ When writing mention HOARD'S DAIRYMAN.

STOP WOMEN

from exercising common sense? You can't do it. As the old rhyme runs:

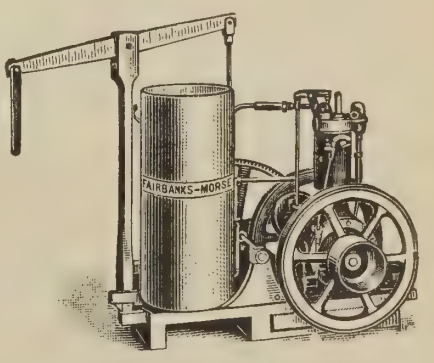
"The man's a fool who tries by force or skill
To turn the current of a woman's will
For if she will, she will, you may depend on't
And if she won't she won't, so there's an end on't."

Common sense tells a woman that when she's sick she needs a doctor.

Common sense tells a woman that in disease the first question is not of man or woman, but of recognized medical ability.

Common sense applied to advertisements which invite women to "write to a woman because she is a woman and understands women," will show the women so appealed to, that it's no use to write to any woman about disease unless that woman is a physician.

Common sense used in the reading of advertisements will discover that no claim is made in them to a physician's knowledge or diploma. And that is not because the claim would be morally culpable as a lie, but because it would be legally punishable as a fraud. The law permits you to masquerade as a doctor in an advertisement, just so long as you don't actually claim to be a doctor, or put M. D. after your name. That's why the advertisement is worded "write to a woman" instead of write to a doctor.



Common sense has brought more than half-a-million women, afflicted with some form of female disease, to Dr. R. V. Pierce as one of the most expert physicians in the United States in the treatment of female diseases. Dr. Pierce is a specialist. He has given more than thirty years of active practice to the treatment of female diseases. Dr. Pierce is not a "physician" by courtesy. He is a physician regularly graduated, legally empowered to practice and with thirty years of experience in the treatment of diseases of women, which he has made his specialty.

The offer of free consultation by letter made by Dr. Pierce i a real offer, an honest offer. It is an offer backed by a medical institution, with a world-wide reputation, a staff of nearly a score of regularly graduated physicians, a practice which reaches every state in the Union and a record of more than half-a-million women treated and ninety-eight out of every hundred perfectly cured.

Write to a doctor. That's the first thing. Write to *the* doctor. That's the next thing. *The* woman's doctor, is Dr. R. V. Pierce, of the Invalids' Hotel, Buffalo, N. Y.

ILLUSTRATION.

Fairbanks, Morse & Co., of Chicago, the well-known scale, gasoline engine and wind mill manufacturers, have recently placed upon the market a remarkable little machine which will be of much interest to all farmers, stock raisers and dairymen. This machine has been very appropriately named a "Jack of all Trades" as it is capable of doing such a variety of work in and about the farm. It consists of a one and one-half horse power gasoline engine, all connnected up ready for work. The following cut

shows the machine with pumping attachment. When water is put in the cooling tank, gasoline in the gasoline tank, and lubricating oil in the oil cups, the engine is ready for work. The gearing can be thrown out of mesh and the engine will then drive machines by belt from pulleys. The machine is particularly valuable on account of being so light that it is easily transported from place to place to perform work wherever it is most convenient to the owner. Among purposes for which this machine may be used are the following: Pumping water, sawing wood, shelling corn, running feed cutters, sewing machines, churns, butter workers, coffee mills, washing machines, cream separators, ventilating fans, dynamos, air pumps, sheep shearing machines, ice choppers, ice-cream freezers, horse clippers, and in fact it is adapted to furnish power for a hundred different purposes. Upon application the manufacturers will be glad to furnish further information in detail and send circulars fully describing the machine.

The Babcock Test in the Factory.

It seems useless to write of the use of the milk test when Farrington and Woll have issued such a splendid book, complete and up-to-date, embodying the principles of the test and the manipulations of it. But perhaps a little experience, coupled with some observation, may be permissible.

Any constant reader of leading agricultural journals, that carry on a question department, will have observed the great number of questions repeatedly asked and especially one that queries, why the variation between test and product is often so great.

It has been repeatedly demonstrated that fat, as shown by the test bottle, will in its commercial form as butter or cheese assimilate about 1-7 of its own weight of moisture. We readily see therefore why all tables add approximately 15 per cent to the fat, in giving the net pounds of butter to be found in the milk. A small amount of foreign matter is also found in the butter, chiefly casesin, which just about balances the loss in separation and churning.

In cheese manufacture, the same rule holds good, only we are dealing with two ingredients of milk instead of one. To find the cheese content of milk with the normal amount of moisture assimilated, as found in good stock, increase the fat by 1-7 and the casein by 2½ and the total will give the amount of cheese in one hundred pounds of milk, when the milk is sound and sweet and free from putrefactive fermentation; that is, in milk ranging from 3.2 to 4.3, which is approximately the range found in the cheese sections.

When this result is not found, when the butter is far removed in excess of the fat, from 15 per cent, or when the cheese falls much below 2.6 or much above 2.75 pounds to each pound of fat, something is wrong, either in manipulation of the test or handling the product.

In gassy milk the yield will often fall much below the figures given on account of great waste in manufacture. I know of no other way to right this in justice than to reject the milk.

Imperfect skimming and faulty churning for butter, or careless working of the curd in cheese, are often causes of great variation of yield in excess of fat. Particularly is this true where milk is of low fat content. For instance: If milk containing 3.3 per cent fat is skimmed leaving .1 and sometimes more in the skim milk, the loss would be at least .03 per cent, while in 4.5 per cent milk it would be only .02 per cent of the total fat.

In cheese the same results are noticeable; when dealing with a low grade milk the per cent of loss is greater than with a high grade. Although the maker is careful and the milk of the best, the actual loss of fat in the whey is about the same in the low as in the high grade.

Another cause for variation of yield, and from observation a fruitful one, is found in imperfect samples. My attention was called recently to a butter yield in excess of the test by over 25 per cent and the manager seemed to think it a remarkable thing to do—almost equaling the famous "Black Pepsin" fraud. An opportunity of examining the samples and the place they were kept was sufficient proof to me of the cause of so much excess. The creamery and churning had been good, but the tests were only made semi-monthly and the samples kept on the shelf near the receiving can night and day for the entire period; much of the cream had risen and firmly adhered to the inside of the bottles and no agency could thoroughly incorporate the fat with the milk to insure an accurate sample. Each sample as tested, would therefore fall short of the true per cent of fat; while the commercial yield was correct, the fat test was short. Samples have also been kept, as the writer knows, in open jars or bottles, for the period of seven or fifteen days, when a constant evaporation was taking place. An experiment with the same milk taken once a day, one sample kept in a tight bottle and another in an open jar, showed a variation at the expiration of fifteen days of .3 of one per cent in favor of the open jar.

Samples may be easily kept fifteen days in perfect condition with a little care.

After each testing, the bottle should be thoroughly cleansed, turned bottom up and dried; the covers whatever they may be, should also be washed and scalded, and each bottle named, or still better, numbered to correspond with the slate number of each patron. I have tried several systems of sampling, but find nothing so easy, simple and accurate as a tin tube about the size of a lead pencil and the length of the can; this is introduced slowly through the milk, the finger placed over the upper end and the contents allowed to run into the sample bottle. Another method of allowing a drip in the conductor, and another of taking out a sample with a small cup or dipper, gives substantially the same results and may be open to less criticism from patrons who are so inclined. It is therefore policy to use such methods as may be found to offer the least possible objection.

After the fresh sample is introduced, sufficient agitation should be given the bottle to clean off the sides any cream adhering. This will not churn the samples providing they are kept in a cool place each day. Our samples are kept in a small refrigerator in the warm months, which need not be expensive, adding a small piece of ice each morning. The box in which they are kept while in use can be placed in the ice box, so that the bottles will not have to be handled.

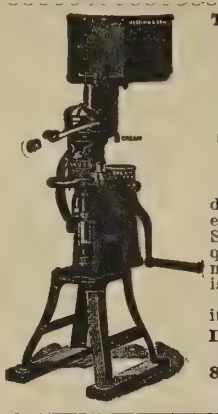
I am sorry to say that we have not experimented with the different preservatives; corrosive sublimate is the base of many of them. We have always used bi-chromate of potash with excellent results, using enough to give the milk a light yellow color; of course, the amount to be used will depend upon the size of the sample.

With the samples in good condition the only secret that I have found in making a clear test and to do it every time, is to cool the samples before adding the acid down to 50 deg. to 55 deg. and in very warm weather to cool the acid as well. The fat will then show clear, the result will be accurate and no wide variation of excess will occur from one test to another.

The modern turbine with the motor separate from the pan is a good machine; a small steam connection, however, should be made into the pan to maintain a temperature sufficiently high that the fat will remain stationary in the neck.

In conclusion, the one great factor in doing work with the Babcock test is Care, *Care*, CARE. It does not require great skill nor great genius, but to carefully follow a few well defined rules; never try to hurry, keep a cool head, do not have other business on hand during the test, do not allow any one standing by to witness the operation to "help;" politely ask every patron to witness the operation as often as he wishes, but as politely tell him that you can do the work better and more satisfactorily than he can.

Do not attempt to do teaching when making the semi-monthly test, but have a



GOOD WHEELS

MAKE A GOOD WAGON.

Unless a wagon has good wheels it is useless. **ELECTRIC STEEL THE ELECTRIC WHEELS** are good wheels and they make a wagon last indefinitely. They are made high or low, any width of tire, to fit any skein. They can't get loose, rot or break down. They last always. Catalog free.

time for it. Do as Dr. Babcock has told us, and with care, coupled with reasonable education and experience, results will be correct.—H. E. COOK, in *Produce Review.*

The Effect of Oleo on Butter.

The assistant dairy commissioner of Iowa gives it as his opinion that the oleo sold in that state reduces the average price of butter at least three cents per pound. As Iowa makes two hundred million pounds of butter per year, it can readily be figured out that oleo causes the farmers a net loss of six million dollars per annum. The production of oleomargarine in the United States has nearly doubled within a year.

Bacterial Origin of Flavor.

Probably in no department of research is a greater amount of investigation going forward, and valuable data and actual discovery being made than in dairy science; and while some of the discoveries have been of little or no value, a wonderful amount of useful and practical material has been placed in the hands of the dairymen. Among the new things announced, since it has been shown how nearly ferments and flavors in butter are associated, is that if certain acids are added to sweet cream, it is not necessary to wait for the development of lactic acid bacteria in the cream, but that it could be churned at once, and churned quite readily, and the true flavor secured. Investigators have been at work on this problem, and an announcement of the results has been made. The most satisfactory result came from using hydrochloric acid diluted in twice its bulk of water, and adding this in small quantities to the sweet cream. Everything was satisfactory, except that the butter had no aroma, though it was pronounced fair and good by the judges. The butter kept well, and had a water content of 12½%; but the low flavor was against it, though not a trace of acid was to be detected, or found by analysis. About the most important thing brought out was that butter seems to be fully dependent upon bacteria for true flavor, rather than the food, provided that the latter is wholesome, and not of a character to impart obnoxious flavors to the milk, which, after all could not be called butter flavor in any sense of the word.—*Mark Lane Express.*

High Pressure in Milk Preserving.

We have given a brief account of the experiments conducted at the West Virginia Experiment Station, in putting milk under a high pressure to aid in preserving it. The pressure seemed to weaken the action of the bacteria which sour milk. We have been interviewing a number of scientific men to try to learn something more about the matter, but few of them are prepared to speak definitely.

Prof. S. M. Babcock says:

"I think Prof Hite has made a valuable contribution to what has been known concerning the conditions which affect the growth of bacteria in milk. I do not see, just now, how those high pressures can be applied in practice but have no doubt a way will be found, if further investigations show that they will be effective in keeping milk in its natural condition. It has been shown before that high pressure retards the development of some kinds of bacteria, but such high pressures as were used in this have, I think, never been tried before. I do not know why pressure should affect the growth of bacteria."

Dr. H. A. Hardy, bacteriologist, says:

"From a practical standpoint, the value of these results is not so clear. From the published account, it appears that the high pressures used did not result in the death of the bacteria, but only in checking their action for a few days. Pressure alone cannot be depended upon to free the milk from disease-producing germs. A combination of pressure with pasteurization gave good results, but in this case, the pressure simply takes the place of the cooling which usually follows the heating. Milk pasteurized at 152 to 160 degrees for from one to three hours and properly cooled and kept cool, can be shipped from New York to San Francisco in good condition. If the extra cost of providing containers capable of withstanding a pressure of ten tons, of applying this pressure and of transporting the container to its destination and back will be less than the cost of properly cooling pasteurized milk and keeping it cool, then some practical results are to be expected from the process. In the subtropical portions of the country, where cooling is more expensive, there may be a balance in favor of pressure; but even here the present outlook is not promising. As the research goes on, something may be found to modify this view."—*Rural New Yorker.*

CONCERNING OUR ADVERTISERS.

The newer counties of Minnesota are receiving a great deal of attention by dairymen and stock raisers on account of their fine meadows and unusual opportunities for stock raising and dairy farming. Illinois, Iowa, Indiana and Michigan are furnishing many new farmers for these localities of which Atkin County, Minnesota, is fast taking the lead. This county is becoming renowned for its fine timothy and clover, and has long been well-known by the stock raising public for its natural meadows of red top and blue joint. This year these meadows are cutting as high as three tons per acre and the crops of timothy and clover are stupendous. Messrs. R. R. Cable and W. G. Purdy, Trustees for the well-known Chicago Rock Island & Pacific Railway Company, are advertising their lands in this county through their land agent, at Minneapolis, Mr. L. B. Arnold. These lands, we understand, can be bought at from $2 to $5 per acre and on unusually easy terms. Mr. L. B. Arnold can be reached at 901 Guaranty Building, Minneapolis, Minn., and we would call the attention of our readers to his advertisement on another page.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

PAPULOUS ECZEMA.

I have a heifer about three years old and has been milking about a year. She is very healthy every way only she has little lumps coming out all around each teat; they are something like grapes, in clusters about each teat. They are not sore in any way; they are soft to the touch and the skin on them is to all appearance like the rest of the udder. There was one little lump came out on one teat like a pea in a little bag; I cut it off with a thread and now it is growing out again the same as the rest of the lumps. This was the first start of it. D. A. P.

Bluevale, Ont.

ANSWER.

You have a definite, clear case of papulous eczema. This is not common to cows teats, but does occur once in a while. Don't allow anything to touch them and then any of the other cows, as you will thus spread the disease. Wash your hands *thoroughly* after *each* touch. Tie a piece of sponge to pencil sized little stick: touch each pustule *only* with butter of antimony; do this for three days once a day, then, instead, use *strong* tincture of iodine three times a day for a week or more.

LAMB DISEASE.

We are having trouble with our lambs and sheep, mostly with our lambs. They are dumpish and lie down a good deal; when they walk it is with head hanging down; after a few days they die. We have opened several, and the inner coating of the stomach seems to be rotten, but is the natural color. The food in their stomach seems to be natural; the intestines of one of the lambs was bloodshot, with no excrement in them. Some of them scour and some seem to be costive. We have just taken the lambs away from the ewes, and put them in a clover pasture. H. E. F. & SONS.

Pine River, Wis.

ANSWER.

You have some of the prominent symptoms of staggers, or sturdy—called also gid—turn sick—waterbrain, etc., etc., caused by a parasite known as *Cœnurus cerebralis*, etc. This affliction often leaves quite suddenly, leaving all O. K.

You have done wisely in removing the youngsters. I hope and believe you have not the above parasitic disease. I incline to believe you have a much less formidable disease. Rub a little of the following between the ears: Common turpentine, one ounce; oil cedar, one ounce; fish oil, three ounces; to be well shaken and rubbed in hard twice a day for a while.

WINTER COAT NOT SHED.

I have a Jersey cow, seemingly in fine health, but has not shed off this spring. What is the trouble? What can I give her to make her shed off? She is fed well, and has green feed twice a day, gives good flow of milk, and is very hearty. J. L. H.

Rockingham, N. C.

ANSWER.

Patience first; daily, long grooming with curry comb and good brush. Flax seed cake and mucilage. If she can stand the depletion, give systematic physicking, at least, one pound of salts and ginger, as per head of this column, six or eight days apart. Then give five grains of arsenic in a little honey and water daily, for three to five days; then rest three to five days; then repeat just once; then give a final dose of physic.

UDDER TROUBLE.—LAME COLT.

A cow on good pasture, in good condition, calved last week. Cow seems healthy and eats well; does not give much milk. Bag is not swollen, but running through udder near skin between the teats, and extending from fore part to back udder is a hard cord formation, about three-fourth inches in size.

Have a two-year-old colt, taken up out of pasture, and seems lame in left hind leg. By a careful examination can find nothing wrong with hoof, and is not swollen or sore in any place that we can find. H. VAN L.

Effingham, Kans.

ANSWER.

No. 1. Paint the cord named with strong tincture of iodine, three or four times a day for a number of days. Internally, give, first, full dose of the physic named at the head of this column. After the physic is through, give sixty grains of iodide of potassa in a little cold water each morning for ten to thirty days.

No. 2. Can form no possible or approximate idea of the lameness or cause. I think the lameness will disappear with moderate rest. Bathe with vinegar and water, half and half, or use strong oak bark tea three quarts, acetic acid, half a pint. Rub in three times a day.

LOSING THE CUD.

I have a cow that is peculiarly affected. Two years ago she was first taken, but it soon disappeared. This spring after calving it returned, but as before did not last long. About three weeks ago it commenced again, and although she eats well, she is losing flesh. She seems to feel well, eats well and looks well, but when chewing her cud it seems to separate and scatters over everything. It looks like a thin, watery paste. We gave her a mild physic (Epsom salts), but it did not seem to make much difference in her condition. C. P. R.

Ridgeway, Ore.

ANSWER.

There are just three things known to me which may be the cause of the condition you name, viz: a carious tooth or teeth, some derangement of the esophagus, or an intermittent inflammation, or other irritation of the larynx, i. e., the top of the esophagus. It might also result, possibly, from some derangement of the pharynx. To find out which, requires a professional, personal examination. You can try a strong liniment around and under the throat, or better, use Gombault's Caustic Balsam; cut off the hair close, raise a blister.

GRUNTS IN COWS.

Have had some trouble with cows from a disease that we call "grunts." Cows simply quit eating for a few days and stand and grunt. Have been having the same treatment as the rest of the herd and no unusual feed. Disease lasts three to five days and they lose their milk almost entirely for this period, and it takes a week or so to get them back to it.

Last fall was when I had the trouble with it. The sick cows were on pasture and fed hay (lucern). W. M.

Vineyard, Utah.

ANSWER.

Give each cow, full grown, four drams of podophyllum and half a dram of nux vomica in three ounces of old whiskey and four of cold water; one dose each day for two days, rest five days, then repeat over again. Two days after the last dose, give full dose of physic to each cow.

Horse Owners! Use GOMBAULT'S Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from **Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING.** *Impossible to produce scar or blemish.*

Variations in Test of Cream.

An intelligent manager of one of our Maine creameries writes that in testing cream twice a month, one test is 17 per cent and the other 17.3 per cent. The patrons cannot see any reason why the test should vary any in the same month.

The manager who writes the above to us well says "the patrons cannot see any reason why the test should vary," etc. The fact is, no one has yet been able to *see* in all cases why tests vary, and yet they vary. Or to put it a little more clearly, no one has yet in all cases been able to see why milk or cream should vary from day to day or from week to week in content of butter fat. Yet it is beyond question that there is a variation in this regard, and the Babcock test will correctly show it. In the case of the milk this is one of the obscure problems over which we may speculate, yet perhaps never be able to clearly see the cause. In making milk with a cow, we are dealing with a living organism, and it is absolutely impossible to know at all times what is interfering with the normal condition of the intricate machinery, so to speak, that is at work from day to day in making up and bringing forth the product of milk. We only know there are variations but cannot know in all cases the cause.

With cream the problem is different and less complicated. The process of taking the cream from the milk is mechanical and largely under the control of the operator. In case of a herd of cows the cream taken from the milk will not widely vary in per cent of butter fat from day to day, week to week, or even from month to month, *when the work of separation has been done precisely the same in each case.* As a matter of fact, however, our work is not strictly uniform, hence slight variations in the contents of butter fat, as shown by the Babcock test, appear. In the case referred to in the opening of this article, the variation of three-tenths of one per cent is small indeed. That much and even more is easily accounted for in the variations due to the person who handles the milk and cream. We cannot in a single article refer to what all these causes of variations may be. Temperature of the tank of water varies the quality of the cream. Time remaining in the water, temperature of milk when immersed, each has its effect. But a still greater cause of a difference in test is the amount of skim milk taken out with the cream. A full can of milk contains twice the cream of course, of a can only half full. Yet in drawing out the skim milk there is as much milk taken out with the cream of the half can as with that of the full can. This is a constantly changing factor as the amount of milk creamed varies from week to week, and of itself alone is far more than enough to account for the discrepancy in the figures given. If all those who use the Cooley tank will carefully study up this one point, they will find many variations of test, now charged to incompetency or dishonesty, fully accounted for.

But there is a variation in the quality of cream that will rise on a Cooley can. The cream from the milk of a fresh cow is richer in butter fat than the cream from the same cow at a late period of her lactation. Hence the cream of a cow will not show the same per cent in September that it showed in April, and may not be exactly the same at the close of a month that it was at the opening. Hence, it would be rare indeed, that a correct test would show exactly the same figures one month that it did the previous, and if so, it would not be common that a test of the last half of the month would be the same as that for the first half.

This matter of the variations in the test of milk and cream has been the cause of much complaint among those who furnish the cream, and also of a wide lack of confidence in the business of associated dairying. That there has been cause for suspicions of injustice in some cases we do not doubt, but a better knowledge of the work involved and longer experience in conducting it, have eliminated the probabilities of error so that when these variations are now encountered, a careful study of possible causes should be made before charging them up to error.—*Maine Farmer.*

Growing Cow Peas.

The following suggestions are intended to apply to Central Missouri and Northern latitudes: Experience has taught us that the methods of handling this crop pursued in the south must be modified somewhat for northern conditions. The varieties best suited for hay purposes here are the Clay and the Black. The Clay produces very little seed, but has a fine leafy vine that is easier cured into hay than any other of the productive sorts. The Black is a rather coarse variety, and usually produces some seed and therefore a slightly richer but coarser hay. The Whippoorwill, so generally used for hay in the south, is a bunch pea this far north (except in very favorable seasons when it vines somewhat) and on this account is not satisfactory for hay. It produces a good crop of grain, however, and is the best sort to grow for hog pasture. The New Era is another excellent variety to grow for hogs, and matures a week or ten days earlier than the Whippoorwill. For green manure, when the crop is to be plowed under, the Wonderful or Unknown is the most productive variety, and is generally used for this purpose. The seed is more expensive, however, and under ordinary circumstances, the Clay will answer quite as well, and at less cost. In buying cow pea seed in the south—the natural home of this plant—all the dealers and farmers will advise the Whippoorwill variety and many inexperienced growers have followed their suggestions, greatly to their detriment. It does not yield a good hay crop in the north.

Avoid sowing too early. This is the most common mistake of the inexperienced, and frequently those who have had years of experience get the crop in before the ground is warm enough to insure prompt germination and rapid growth. If these conditions are not secured, weedy hay will be the result. Cow peas must have high temperature, to outgrow the weeds that spring up.

No date for sowing can be fixed. The best rule is to wait until all the corn is planted and the soil has gotten thoroughly warm. If corn planting is delayed on account of the backward season, delay cow pea sowings. We have very seldom had good results from sowing earlier than June 1, and this year our best prospects are from sowings after June 15. We have had splendid results from sowing as late as July 15, although this is usually too late for a full crop. We aim to sow as near June 10 as possible in the average season.

The land should be prepared about as for corn, and the best results will be obtained by either allowing the weeds to get a good start before breaking the land or break about corn planting time and cultivate occasionally afterward to destroy the weeds. Have the land clean and freshly cultivated on the surface at the time of seeding. Sow at a rate of at least a bushel and a half per acre, either broadcast and cover deep with a walking cultivator or spring-tooth harrow, or, what is much better, sow with a wheat drill set from two to three inches deep, all hoes running. With an abundance of moisture in the soil two to three inches deep will answer, but if dry they should be covered three inches or more.

After seeding, the crop must be left to its own resources, as it is very difficult to do any effective tilling, especially after the plants are up. In favorable weather they will germinate very quickly. If, however, germination should be delayed by cool, wet weather and a crust forms on the surface and the weeds and grass begin to grow before the cow peas are up, a smoothing harrow, light drag or other shallow-tilling implement should be run over the surface promptly to break the crust and kill the young weeds. This is very important and should never be neglected; otherwise a reduced yield of weedy hay will be the result.—J. A. WATERS, in *Breeder's Gazette.*

THE JONES UMBRELLA "ROOF."

A NEW UNION TWILLED SILK "ROOF" $1.00

RE-COVER YOUR OWN UMBRELLA.

The Adjustable "Roof" fits any frame, requires no sewing, and can be put on in a minute. You can re-cover your own umbrella without the slightest trouble or moments delay.

Take the measure (to the fraction of an inch) of your old umbrella; count the number of outside ribs; state if the center rod is steel or wood; send to us with $1.00 and we will mail postpaid, a Union Twilled Silk 25 or 26 inch Adjustable "Roof" (27 or 28 inch, $1.25; 29 or 30 inch, $1.50). Umbrella "Roofs" all sizes and prices from 50 cents to $8.00 each, according to quality. If you are not absolutely satisfied in every particular, send the "roof" back, and we will refund the money *at once*, including stamps you have used for postage. Over a quarter of a million "Roofs" sold.

Booklet, "Umbrella Economy" with simple instructions necessary with your order.

All first-class dealers sell Jones Umbrella "Roofs."

The Jones-Mullen Co., 396-398 Broadway, New York.

Manufacturers of the highest grades of Umbrellas to the largest stores in the world.

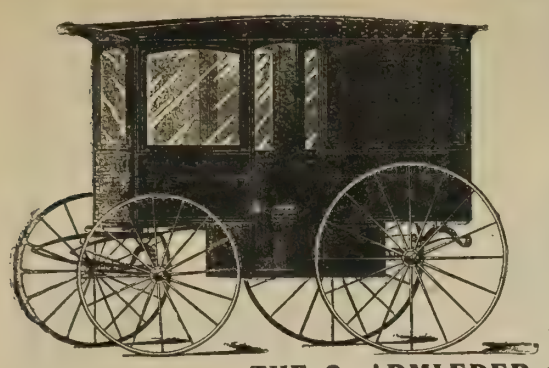
ILLUSTRATION.

A REMARKABLE OFFER.



A famous philosopher once said "Simplicity is the soul of greatness." We more than agree with him, for we would extend the principle so as to apply it to machinery as well as to men. The simpler the construction of any machine, consistent with efficiency and durability, the better. This is recognized by the principle manufacturers. We note that the manufacturers of the "New Hero" Ensilage Cutters make this remarkable claim: "Our Ensilage and Fodder Cutters have less working parts than any similar machines, and yet, because of the great strength and durability of each part, they are heavier than any others of the same size. They have every improvement essential to effective and rapid work, and every advantage which can honestly be claimed for any similar machines. They excel in simplicity of construction, strength, durability, lightness of draft and effective working qualities." After calling attention to the adjustable spiral springs, hardened steel cutting plate, hinged ensilage table, simple and effective device for throwing in and out of gear, perfectly reliable safety balance wheel and pully, and extraordinarily strong frames, shafts, etc., with which their ensilage cutters are equipped, they make this following remarkable offer:

"We believe that deeds are more convincing than words. Therefore we back up our statements with the standing offer to send any of our machines on trial, or in competition with any similar machines rated at the same capacity, to any one who will furnish bona fide references as to responsibility, etc., and if they are not found to be in every way as represented by us, and to be stronger and more durable and to do better work than any similar machines rated at the same capacity, they may be returned at our expense."

They make ensilage cutters in a sufficient variety of sizes to fill any requirements, and when desired, equip them with carriers or elevators of any desired length. Their carrier is called an Universal Swivel carrier because it can be run at any angle in front of cutter, or straight away, and can be changed in a moment's time from one angle to another even when the cutter is in operation. An excellent illustration of their cutter and carrier is shown herewith. Their advertisement will be found on another page.

This same company make a complete line of horse-powers, both sweep and tread, for operating these cutters and other machines, twenty-six sizes and styles of grinding mills, a complete line of corn shellers, corn huskers, wood saws, windmills, etc, all of which are sold subject to the remarkable offer quoted above. They offer to send their 160 page illustrated catalogue, fully describing all their machines, to any of our readers who will write them specifying their needs. Address APPLETON MFG. CO., 35 Fargo Street, Batavia, Illinois.

A Perfect Milk Wagon

On a Perfect . . . Short Turning Gear

WE make the only drop center wagon that has a self-balancing, short turning gear. All parts are wrought iron forgings. It is so plain and simple that it can't get out of order and if any part should break, any country blacksmith can easily repair it. All other wagons of this kind have complicated gears, and mostly made of cast iron.

Write us for our Catalogue, which fully illustrates and describes this wagon and 10 other styles.

THE NEW BOOK
Feeds and Feeding

By Prof. W. A. HENRY,
Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

SMALLEY MFG. COMPANY, Sole Makers, MANITOWOC, WIS.

MAKE ONLY

SWEET ENSILAGE

Ever since the ensilage system has been introduced in this country it has been the ambition and effort of silolists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste.

The best way to Shred Ensilage is with the

St. Albans Ensilage and Fodder Shredder.

It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail free a pamphlet on the subject.

ST. ALBANS FOUNDRY CO., ST. ALBANS, VT.

DAIN THE BEST, THE CHEAPEST, THE STRONGEST, THE MOST DURABLE **STEEL CORN CUTTER.**

A PRONOUNCED SUCCESS---THE VERDICT IS UNANIMOUS.

"PURIFINE" A BOON TO THE GREAT DAIRY INTERESTS,
A POWERFUL **Disinfectant** That is ODORLESS, NON-POISONOUS. Used in Creameries, Cheese Factories, Dairies and Stables.
IT DOES NOT Create an Oder to Destroy One.
SAN FRANCISCO, Sept. 22d, 1896.
I have used "Purifine" in cleansing milk cans and bottles and find it will remove the bad odor left by old sour milk more effectually than anything I ever tried.
E. A. GREEN. Sec'y,
Millbrae Dairy Company, Mission & 9th.
Applied with large quantity of water, which makes it cheap and convenient of use. It is invaluable to the cleanly dairyman or factory operator. Once try, you'll never be without.
SEND $1.00 FOR SAMPLE GALLON by Freight.
This powerful disinfectant creates no odor of its own, but will keep creamery, cheese factory and dairy pure and sweet. TRY IT ONCE.
FITCH CHEMICAL COMPANY, Bay City, Michigan.

. . A Square Talk . .
For some years the dairy farmers and creamerymen have felt the pinch of hard times to such an extent that they have been buying the lowest priced articles the market afforded and they have had to renew them every year. Our great factory and immense output enable us to put on the market a line of dairy supplies of the highest quality at first-cost prices, no higher than the poorer ones, and with good lasting qualities.
DAIRY SUPPLIES . . . Our VATS and CHURNS are unsurpassed. We carry in stock the well known SHARPLES CREAM SEPARATORS which can be run profitably with a dairy of only five cows. The No-Tin Six-bottle Babcock Test that will do accurate work and last a life-time.
WHEN BUYING AN OUTFIT
It will pay the intending purchaser to specify that it shall be of the Haney-Campbell make. Order from your nearest dealer if you prefer, and he will send to us for it Catalogue on request.

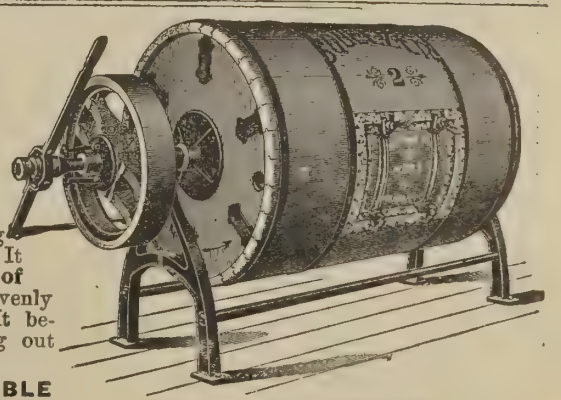
THE
MOODY-SHARPLES SYSTEM
For the Creameryman and the Dairy Farmer

Compliments of.....
P. M. Sharples
The Sharples Co., Canal and Washington Sts., CHICAGO, ILL.
West Chester, PENNA., U. S. A.

If there is no creamery in the neighborhood;
If there is a gathered cream factory;
If the supply of milk is limited;
If you will send for a Moody-Sharples pamphlet, we will mail it to you free and it is full of "meat" and "pointers" to increased prosperity.

THE MOODY-SHARPLES SYSTEM
Was an experiment two years ago. A proved and an immense success to-day. The original factory at Nashua, Iowa, has never made a skip. Successful from the day it started it has increased in profitableness, in patronage, and in value to its patrons.



Its value as a demonstration, practical and beyond dispute, of the merits of its system to dairymen everywhere, is incalculable.

Its unparalleled opposition from competitors, willing to spend any sum to down it, coupled with the impotent attacks of a jealous corporation, has increased its value, as an example of what it is capable of doing, more than a thousand fold.
"A jewel tested by fire is a jewel indeed."
The Moody-Sharples system *is* a *system*, and must be adopted as a system, or its full results cannot be attained.
Send for one of the Pamphlets, and Catalogue No. 46.

Reading notices, 50 cents per line (nonpariel measure) each insertion

"Cemelain," a new coating for butter tubs, has been given a somewhat extensive trial by a Minnesota butter maker, with discouraging results. The tubs stripped well and there was no mold, but it is stated that it gave a most vile flavor to the butter where it was in contact with the cemelain. This may be remedied by improvements in the methods of manufacture of the article, but the outlook is not promising at present.

According to a letter in the *Country Gentleman*, the Wheeler Separator Company, of Syracuse, N. Y., is demanding a royalty from dairymen of New York who are using the dilution method of separating cream, claiming that they have a patent on the process. Seeing that every experiment station and dairy authority in the country have condemned the process and cans as useless and wasteful, it is strange that so many dairymen still bite at this fake and submit to be buncoed into paying a royalty for using a process that is not and cannot be patented. Verily, a fool and his money are soon parted.

A correspondent of the *National Stockman* is evidently somewhat uncertain as to what a starter is. He quotes from the Dairyman an article on sweet curdling of milk, where the use of a starter is advocated, in connection with a thorough scalding and washing of dairy utensils, as a remedy. The correspondent declares this is all wrong and then describes his method of cooling the milk and using sour milk, for ripening the cream as a cure for the same trouble.

We should advise the writer to investigate a little as to the definition of terms, before he makes another jump in the dark. He reminds us of the man who talked prose all his life; without knowing it.

A PRIZE MEDAL DAIRYMAN.

Every year Hoard's Dairyman offers a silver medal to the Short Course student in the Wisconsin Agricultural College who makes the best score in the annual contest of judging dairy cattle. In every instance the young man winning the medal has made a subsequent good showing of himself, and this fact has encouraged us greatly in maintaining the offer. The winner of the medal the present year is Mr. J. W. Wagner, of Hillsboro, Wis., who on receipt of the medal, writes us the following pleasant letter:

W. D. Hoard:

Dear Sir:—Please accept my sincere thanks for the Hoard's Dairyman medal, which I received today. We have a small dairy of grade Holstein cows, having now our third pure bred sire, and as I am more interested in the dairy cow than any other farm stock, this medal has been especially coveted by me.

I attribute my success in securing this medal, in no small part, to information secured through the columns of the Dairyman, of which I have been a subscriber for a number of years, and have always considered it the leading dairy paper published.

I think the Short Course is a grand thing for the young farmer, and had wanted to take the course myself before I did, and am glad to know that so many of our citizens take enough interest in the Short Course to offer the medals that they do.

Wishing the Dairyman unbounded success,
I am, yours very truly,
J. M. Wagner.

The Dairyman wishes that there were a thousand young, brainy, ambitious farmers in Wisconsin every year, who would contend manfully for this medal. The growth of the state, and every other state as well, in true agricultural prosperity, depends on the amount of pride the young farmers take in their own intellectual development and growth, in knowledge of this business we call farming.

It is a sad state of things when the sons of farmers despise the farm, and come up with the idea, that the only place for them to show how smart they are, and what ability they possess, is in some other business than farming.

If we can keep up the pride and ambition of the young farmers, the farms will grow in fertility and value, and the state will increase gradually in the strength of its manhood and civilization.

All of our educational, professional, and political forces should feel a lively sense of responsibility, in promoting the agricultural ambition and mental equipment of the young farmers of the state.

A GROUP OF DAIRY COWS.

Property of C. C. Smith, Lima, Ind.

A Lesson In Hog Feeding.

Ed. Hoard's Dairyman:—I was much interested in the article on "Hog Feeding," by J. G. Haney, on pages 432 and 433, of your issue of July 14th, and I fully agree with, and endorse *every* word he says, and only wish that said article *could be read by every hog raiser in the United States.* When will the average farmer learn, that, to treat a hog *humanely* will put *dollars* into his pockets, that now only "rattle" with the chink of *pennies*; or are so empty there isn't a single rattle except, mayhap, of "tobacco tags," in them. The time, I am happy to say, is rapidly passing, on many of our farms, when, "any thing is good enough for a hog."

Stagnant, foul water, moldy corn, rotten potatoes and all other refuse of the cellar and kitchen, with the vilest sleeping quarters imaginable, reeking in filth, or infested with vermin, were often his only share of the proceeds from the abundance of broad acres, well tilled fields and overflowing granaries.

And why? O! simply because he was "nothing but a hog," subject to his owner's caprices and neglect and had no voice in the matter of expressing his likes and dislikes.

He was *par excellence* the "farm scavenger" and as such relegated to a place with the "buzzards" and other carrion destroyers.

Then there came a time when corn was such a drug in the markets that in some sections of our country it was used as fuel, at seven cents per bushel, (cheaper than either wood or coal.) Then it was shovled out to the hogs in unstinted quantities, and in the mud and filth of circumscribed feeding lots in fall and winter, or in shadeless fields when the mercury was "cavorting" around "nineties". With what results?

Examine the census reports of the Agricultural Bureau for your answer. "Hogs dying by the wholesale," from hog cholera? *No!* From the ignorance, the shiftlessness or the neglect of their careless owners. (I put it strongly, but I know whereof I speak.) "Experience is a dear, as well as stern, schoolmaster." I well remember some twelve years ago, my husband was feeding for the September markets, (we did not sell every month in the year as we can now) an *unusually fine* "bunch" of hogs, all Poland-Chinas, bred on our own farms, black, shiny and uniform in size.

The first week in August, the tenant on the "feeding farm" came up to town early one morning, breathless, with the startling anouncement—"Mr. Busick! The cholera has broken out among your fattening hogs?" "There's six of the finest dead and nearly all the rest are sick!" Post haste, the offices of the druggist were called into requisition and the man departed with all speed, laden with cholera remedies sufficient to kill the balance, Mr. Busick following after as soon as possible, accompanied by myself.

On the way down I gave my husband my ideas as to what ailed his hogs, and when we reached the feed lot, a sorry sight met our view. The poor, sick panting creatures, confined in that treeless, shadeless lot, had greedily devoured the nauseous mess prepared for them, and were lying around in the boiling sun, sicker than ever, awaiting in their dumb agony "the kindly touch" that would end their misery.

I exclaimed, "they have no disease! They are simply starved for proper food, and roasted alive! Between the hot corn inside and the hot sun outside, they are absolutely cooked, and with broad acres of clover, knee high, all around them! It is nothing less than sinful," and woman-like I burst into tears.

Turning to me my husband said, "What would *you* do?" I answered, "bury the dead and turn out all the living that can walk." In less time than I can write it, two panels of that feed lot fence were smashed and the living hogs turned into the clover and how they went for it! With what result? Seventy-five, out of 200, were marketed inside of two months, as fine healthy porkers as ever traveled to Chicago.

Of course, among the neighbors, the "*dope*" as all hog medicine hereabout is usually called, got the credit for the recovery of the seventy-five, but I knew and my husband finally admitted, that those hogs with oceans of feed and shade all around them died from heat and starvation.

A post-mortem, held on several, revealed the fact that the intense heat had melted the interior fat, as it ran out in streams when the animals were opened. Needless to say that "hog feeding," on our farms, thereafter, underwent a radical change. All the animals are provided with shade and a variety of foods, the year around, and never a sick or ailing hog has been known. "The merciful man is merciful to his beast," be it covered with wool, hair or feathers, and as a reward his bank account will increase.

Kate M. Busick.

Wabash, Ind.

To Breed Healthy Hogs.

The most feasble plan to my mind would be to advance by going backward until we reach a conservative point between the lank, active hog of the pioneer age, which possessed a vigorous constitution and an immunity from disease unknown among the swine of today and the present condition of his overburdened descendants. If we choose as breeders only those of sufficient bone, sound feet and legs and good muscular action, and give all hogs a sufficient range; breed out all excess of coarseness, with just enough shoulder to give symmetry to the animal, also avoid inbreeding and over-feeding in close confinement; give all hogs a free grass range during the growing season, and all the changes of food at your command, especially during fall, winter and spring, we will, in time, bring about the desired result. It is absolutely impossible to produce a large proportion of lean meat without the animal has ample bone, sound feet and legs, with organs of digestion and respiration unimpaired, thus insuring constitutional vigor and muscular action. Muscle is lean meat and is developed by exercise, and the vigorous, active hog during the fattening season, is taking on flesh of that streaked kind, firm and fine in texture, with equal facility that his helpless, weak-legged brother takes on his bunches of flabby fat.—*Ex.*

THE California State Fair had as one of its features a model silo, which was fully explained in all the details of its construction and operation. A good many men would welcome a demonstration like that.

AFTER a dairyman has allowed his milk to taint by letting his cows stand in a rotten, fermenting pool of water and mud; his cream to spoil by dirty utensils and surroundings, he should not exhibit any surprise that his butter does not bring the highest price and rank as "extras".

TWENTY-FOUR out of 104 samples of milk in Indianapolis were found to be poisoned with formaldehyde, put in as a preservative. The venders of these twenty-four samples have all been arrested, and every case of like character will be vigorously prosecuted. This is as it should be in every city and town in the country. Any man who will sell poisoned food should be made to feel the full penalty of the law.

THE Woodstock, Illinois, *Sentinel* mentions the fact that a veterinarian of that state recently declared seventy-nine cows to be affected with tuberculosis and upon being slaughtered only forty-nine were condemned. The Agricultural editor of the Whitewater, (Wis.,) *Register* very pertinently suggests that in all such cases the veterinarian be made to pay for all cattle found to be in a healthy state. The suggestion is a good one. Such a course would make some of these veterinary flash lights a little more careful of their verdicts.

SOME OF THE VALUABLE ARTICLES IN THIS NUMBER.

We wish to call the attention of our readers to some of the especially valuable articles to be found in this issue. Not but that each issue is valuable to him who hath the teachable heart and mind, but every star has its points, even though they do not afford all the light it gives. We wish to call attention to the article, "A Lesson In Hog Feeding," on page 527, by that splendid dairy woman, Mrs. Kate M. Busick. There is a world of valuable suggestion in it to the farmer whose heart and pocket are in human accord. We know it will meet the hearty endorsement of one of the wisest men that ever handled hogs, Theo. Louis.

Then there is the advice of the Purdue Experiment Station, against being humbugged by the "Milk Dilution Separators." It is to be hoped that none of the readers of HOARD'S DAIRYMAN will be taken in on this thing. Solomon said: "The wise man foreseeth the evil and hideth himself, but the foolish pass on and are punished." We sometimes think that there is a large class of farmers who had rather be humbugged out of $50 than to spend $1 for information that will enable them to "hide themselves." Then there is the short but pithy experience of A. E. Helmer, of Jefferson Co., N. Y., on page 534. He tells a significant story to the man who cannot see that it pays wonderfully well to spend a little money on a better dairy education. That grand old agricultural saint and teacher, Prof. I. P. Roberts, sends out a flood of good wholesome light on "Feeds and Productivity," page 534. We sincerely pity the man that can read what he says without appreciation and benefit.

Prof. Henry lets in a ray of real light on the cause of so much loss of cattle in the feeding of ripe corn stalks. Has any one ever found saltpeter in corn ensilage? Besides, there is a plain, meaty bit of farm experience from our correspondent, W. J., of N. Y., page 530. W. J. is a believer in the doctrine that it is wiser and more profitable from the cash standpoint to cultivate one acre well than ten acres poorly. Such farmers are always larger than their farm. It is better to have "expansion" come that way. There is more money, honor and brains in it. Then "Our John," John Gould, fills his "Note and Comment" full of good thought, experience and quaint conceit. It is well worth the time of any dairy farmer who, as the old Hosier said, "fills his socks with sound feet" to think over what Mason Parmalee said to John about the fly and soiling problem. When the DAIRYMAN started the talk some years ago about the economy and profit of using the silo to soil cows in summer, a great many dairy farmers shook their heads that are nodding them with approval now. "'Twas ever thus from childhood's hour." We all must "live and learn."

What a mint of solid valuable conclusion is the patient figuring upon the cost of certain grain crops, page 531, by the Wisconsin Labor Commissioner, Halford Erickson. For less than two cents a farmer can see here what would cost him many dollars if he figured it out of his own experience. But it is with acres of grain as it is with cows. It is the fertile acre and cow that produces at the least cost. Produce a good cow and make the land rich, and keep no shirks in either, if you want to make money out of them.

THE RELATION OF MILK TO HEALTH.

HOARD'S DAIRYMAN has received a letter from one of its Southern readers, which reports an unusual amount of sickness at Meridian, in Mississippi, with a request that we would furnish such information as could be had concerning the possible danger from using milk from cows kept near or in that city and feeding upon such grass and offal as they could find in running at large. It was stated that the water in the streams was very low and more or less defiled by sewage from above, as well as by local customs. Inquiry was also made concerning the preparation known as "Liquid Milk Sweet" and other preservatives to prevent milk from souring.

Apart from the introduction our reply was as follows:

Answering your specific questions we have to say that it very seldom happens that the feed or drink of a cow so directly or seriously contaminates her milk as to make it particularly unhealthful. Nature, ever bounteous, provides that the milk secreted by the mother shall not be so much at the mercy of her environment as to jeopardize the life of her offspring. It is true that the modern milch cow, as well as the modern human mother, are subjected to demands and conditions, not altogether in accordance with nature's plans, and we accordingly find that fright, exposure, ill treatment, or other matters which affect nerve conditions, sometimes so seriously affect the milk as to produce quite marked results in those who depend exclusively or largely on milk for sustenance.

In other words, the character of the food furnished the milk-producing mother—other conditions being unobjectionable—does not ordinarily affect the milk primarily, but may in time so affect her physical condition as to do so. If, therefore, the sickness which prevails in Meridian is in any degree attributable to the character or condition of the milk served to your people, we should expect to find the cause in some contaminating influences operating at the time of milking the cows or subsequent thereto.

If the prevailing diseases are of bacterial origin, this contamination might occur from the cows wading in the filthy streams or low, wet places, or gathering up bacteria on their udders and flanks in other places, and having these dislodged at the time of milking. Or, it might come from the use of impure water in washing the milk utensils, or diluting the milk; or from the filthy hands or clothing of the milkers.

On the other hand, if the sickness seems more attributable to defective digestion and nutrition, and is especially prevalent among milk-fed children, we should incline to the opinion that preservatives used were largely responsible. We have no special knowledge as to the composition of this "Liquid Milk Sweet," but if it will do what its promoters claim for it, there can be no question, as it seems to us, of its injurious properties. Whatever will "preserve" milk must necessarily lower its degree of digestibility, and the continued ingestion of any chemical of sufficient potency to destroy bacterial life or prevent its growth cannot be otherwise than fraught with ultimate, if not immediate, danger, and this more particularly to those whose habits of life and occupation do not tend to the excretion of such matters, as one of the results of active exercise.

PARAFFIN OLEO.

Numerous references have been made in the DAIRYMAN as to the use of paraffin in oleo. On another page of this issue will be found a more detailed report as to the amount which has been found, together with its use and probable effect on the system. It is an excellent example of the manner in which the makers of oleo are constantly on the look out for methods to improve the appearance of their product (which the paraffin undoubtedly does) even at the expense of the health of the consumer. As paraffin costs about six cents per pound, there is also a chance to cheapen the cost of oleo. On the amount of oleo made last year, ten per cent of paraffin would amount to 8,780,000 pounds and the above amount bought at six cents and sold at twelve cents per pound, would amount to the nice little profit of $526,800, in addition to the regular profit of manufacture—a nice little sum and well worth trying for. But every pound of paraffin used means a pound of butter the less, a powerful factor in lowering prices of creamery butter and a consequent general demoralization of the dairy business—to say nothing of the unhealthfulness of the paraffin. If the dairymen of the country do not put up a good strong fight against this paraffin oleo, they may as well sell their cows and stop making butter, for there is enough raw material in the country to make a substitute for every pound of butter now made.

A Bad, B-a-d Break.

The cloven hoof of the oleomargarine manufacturers has been uncovered at last.

These innocent and much imposed upon benefactors of humanity have always maintained that they did not approve of the sale of oleomargarine for butter. "Oleomargarine," they said, "is perfectly able to sell upon its own merits." This is what they said when they were fighting the anti-color laws.

But they knew all the time, that if ever the sale of oleomargarine, as butter, was stopped, their business would be gone. They know that they instruct their agents to advise retailers to sell oleomargarine for pure butter. But heretofore they have done it in an underhand manner, while still maintaining an outward show of honesty of purpose. But when they saw the effects of a letter of warning, sent out to retailers by the Illinois Dairy Union, in which they were cautioned against selling oleomargarine for butter, under penalty of prosecution under state laws, their frenzy knew no bounds. Visions of an immense fraudulent traffic the coming winter, began to fade from view, and one, less wise than his associates in the Oleomargarine Trust, in a moment of uncontrollable passion, let the cat out of the bag through a letter which contained the following:

"The internal revenue department looks after its own business and the state after its, and should this so-called Dairy Union interfere with your business, in way of prosecution as to the state laws, we hereby guarantee you protection to the extent of paying all fines, costs, etc., until the color law is decided constitutional, by the supreme court of the state of Illinois, and will, further, upon receiving complaint, take such action for damages, as will make it unpleasant for some of those who are attempting to interfere with your and our own legitimate business."

In the letter sent out no threat was made to prosecute under the anti-color law, now tied up in the courts. The law this manufacturer promises to protect his customers from, is a branding law, simply forbidding the sale of oleomargarine for butter, and the kind of laws the oleomargarine men have always maintained they approved of. While they have, in an underhand manner, always fought these laws, this is the first instance in which they have ever openly acknowledged they are a party to the fraud being practiced by retailers, which has brought the business into such disrepute.

This letter is a valuable addition to the National Dairy Union's collection of evidence of the connection of the manufacturers with the disreputable practices of the retailers.—*Chicago Produce.*

Foaming Milk.

ED. HOARD'S DAIRYMAN:—My neighbor has two Jersey cows, one fresh with calf; their milk for nearly a year, both night and morning, gets very frothy when the cream begins to rise, and in taking off cream it is lumpy. Both cows milk froths, as they have tried keeping it separate to see if it came from one, but both acts the same way. They asked me what caused it and I told them that it was probably caused by the cows eating straw from manure pile. But they fenced it off from lot to keep them out, but the trouble continues. The milk is rich, tastes all right, and looks all right, but still it will get frothy. They keep the cows all day on grass and at night they are in stable lot. Cows are healthy, eat well, and give a quantity of milk. The milk is not

frothy when milked, but gets frothy just as soon as it begins to cool and the cream commences to rise. M B. L.

Paris, Ky.

It is hard for dairymen to rid themselves of the idea that feed is responsible for the various troubles they find in the milk pail and churn. Unless an animal has been fed on abnormal foods such as fermenting brewers grains or distillery slop, until disease has been produced; or unless there is a local disease of the udder, the quality of the milk as regards the ferments which are to act on it, is not changed by the food given. The various abnormal changes which take place in milk or cream during the process of manufacture into butter, are not due to any quality of the food or water, but entirely to the conditions under which the milk is kept. The various abnormal diseases of milk, whether ropy, sweet curdling, blue or red colors, or in fact, any of the changes which dairymen complain of so frequently, are caused by bacteria of various species, and these can be removed and their action prevented by a liberal use of hot water, soda, light and air, in and around the stables and milk utensils.

In the above case it is more than probable that some kind of yeast has got into the milk and caused the foaming, from fermentation and formation of gas. A thorough cleaning and scalding of the milk utensils together with a thorough brushing of the cow, and wiping of the udder with a damp cloth, before milking, will get rid of the difficulty.

A GOOD IDEA.

To obviate the danger of infection from the use of old milk tickets, the milkmen of Winona, Minn., have adopted the following system:

A card is furnished for one dollar, on which there are twenty tickets printed. For each quart of milk one of these tickets is torn out and the tickets are never used a second time. The idea is that in the use of the old tickets, the tickets may go into a family where there is some contagious disease and then after being collected be given out to some home where they will start the disease. This, of course, cannot be the case where tickets are used but once.

Cow Peas for Wisconsin.

F. G. Burlington, Wis., writes: "The dairy papers recommend the cow pea for cows and I bought a bushel of seed from an agricultural dealer, planting the same on a half acre of ground. The vines are now in blossom. I do not think I received the kind of seed ordered and write you for information. I inclose leaves, blossoms and some of the original seed. I ordered cow peas, but the plants have only grown from six to twelve inches high, and look more like a bean than a pea. Please inform me if these are cow peas, and whether a mistake has been made or not."

The samples received show that our correspondent has received just what he ordered. The seeds of the cow pea plant resemble a bean more than they do a pea, and the plants also look considerably like beans. The writer of this reply regards the cow pea vine as a plant of some promise for Wisconsin, but only in a secondary way. In the southern states where clover cannot be grown, the cow pea vine is quite useful, as it gathers up much nitrogen in the air, and fixes it in roots, stems and leaves. These, when turned under by the plow, enrich the soil. The cow pea vine will furnish from three or four to eight or ten tons of green forage per acre, making from three-fourths of a ton to a ton and a half of hay of fair quality.

For Wisconsin purposes in general, the cow pea vine is far less useful than red clover. Our farmers have had a good deal of trouble in getting red clover seed to catch during late dry years and for this reason they have turned to other plants as a partial substitute. If we would go to the expense and give the same attention to red clover as we do to such plants as cow peas, ect., which we often attempt to use as substitutes for the clover plant, we would be far ahead. It is recommended that our correspondent cut the crop when the seeds are partially formed and note how much hay he secures from the crop. It will probably be considerably less than the returns of clover hay would have been under the same conditions.—W. A. HENRY, in *Wisconsin Agriculturist*.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

SUMMER FEEDING.—AN APPEAL TO J. E. G. OF ONTARIO.

I see that "J. E. G.," on page 496, last issue, says he is keeping thirty-four to thirty-six head of cattle on a 120-acre farm. He is getting there. I believe he will soon increase that to nearer fifty. Would like to know if he has adopted soiling for cows in summer, and his results; what he feeds and how he keeps up the supply of green feed; and what grain, if any, he feeds. W. K. M.

Perth Co., Ontario.

We hope J. E. G. may find the time to give this inquirer and other readers the information sought. Meantime we may say that the article on page 496 indicates that the summer silo has been of marked advantage. It is perhaps as much of an improvement over former methods of soiling as the winter silo is an improvement on all dry fodder for winter.

The same inquirer asks whether it would not be well to keep cows in the stable during the day in summer and let them out at night. This will depend somewhat on the character of the stable, and the condition of the weather. Cows need to be bathed in sunshine. It is always economical to feed them in the stable, but when it is not cold or stormy, or scorching hot, and flies troublesome, cows should have a daily sun bath.

FEEDING SKIM MILK TO COWS.

I should like to know your opinion on feeding skim milk to cows, when to feed and how. Could it be made to take the place of any of the concentrates, such as wheat bran? I am pretty nearly convinced that a hog is a nuisance on a dairy farm. I should also like to hear through the columns of your paper from any subscriber who has had experience in this line. WM. T. S.

Lincoln, Va.

Skim milk is an excellent feed for milch cows, and may be fed at any time. Ordinarily cows have to acquire a liking for it. We have had success in inducing this liking by putting a small quantity in a pail and covering it pretty deeply with bran or meal, and before long cows will get to drink the skim milk clear, and as ravenously as any calf. Ordinary skim milk usually contains not less than three per cent of digestible protein. Eight pounds of skim milk would therefore easily take the place of two pounds of bran.

But a few years ago we had full reports of experience with feeding skim milk to cows. One of the most successful dairymen in New York, Mr. Menzo Wilcox, makes no other use of this product.

WHEN TO CUT KAFIR CORN FOR SILAGE. AMOUNT REQUIRED FOR FORTY COWS.

In what stage does this kafir corn want to be cut to make silage? I have eight acres of kafir corn. I have one round stave silo, ten feet in diameter, thirteen feet deep, and one square one 9×13 and 13 feet high. Is that large enough for forty cows, and how many tons will these two hold? I want to fill one with the corn, and the other with stock peas. I have twelve acres of peas and corn mixed, with which I want to fill one of them.

Princeton, Ind. G. W. K.

Kafir corn is at its best for silage just as the grain is preparing to ripen. Under ordinary conditions this will be about the time the lower leaves on the stalk become dry.

The silos mentioned are not deep enough for best results. Twenty feet in depth is the least that should be accepted, unless the top is pretty heavily weighted at time of filling. Silage to keep well, must be well compressed. This is necessary, as well to force out the air, as to keep it out. Thorough tramping helps to do this, just as it helps to settle hay in a mow or stack. This is especially necessary at the outside and corners.

If these silos could be refilled after the first settling, they would hold, respectively, about fifteen and twenty-two tons, or thirty-eight tons in all, and not enough, by any means, for forty cows, except as a relish. Of course, ten pounds of silage per day is much better than to have no succulent feed, but twenty pounds per day would be better, and thirty pounds per day none too much.

NEBRASKA QUERIES.

I want you to send me a feed ration, for a cow that will weigh twelve hundred, of wild hay and good oat straw, (is it good to cut up straw,) and plenty of timothy and clover hay and alfalfa, and plenty of millet and sugar cane with wheat bran. I want two rations made, regardless of cost. Is shorts good for a milk cow, and how much at a feed? I have plenty of oats and corn meal and rye; how many pounds for a cow, to make her give milk, and the quantity and quality.

I have a cow seven years old, that was fresh the third of this month. She gives six gallons of milk a day, and is subject to garget, and I want to know if there is any way to prevent it, and what to do for it.

I also have a cow that will be fresh the 7th of December, and one of her hind teats does not milk good. Now do you think that it will be all right when she is fresh again as it has not been hurt. She is three years old.

Humboldt, Neb. M. C. D.

Where one has plenty of good clover and timothy hay and alfalfa he does not want to be feeding wild hay and oat straw to cows in milk. Where nothing better than wild hay and oat straw is available, they can be made serviceable, but only at greater expense for the grain feeds which are rich in protein. We submit the following as a fairly good daily allowance, to be given in two equal feeds, one at night and the other in the morning:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
10 pounds clover, and timothy	8.58	.48	3.96	.16
10 lbs. alfalfa	9.16	1.10	3.96	.12
4 lbs. bran	3.52	.50	1.54	.12
4 lbs. oats (ground)	3.56	.37	1.89	.17
4 lbs corn (ground)	3.56	.31	2.67	.17
Totals	28.38	2.76	14.02	.74

This is a liberal allowance for a large cow, but if she is an extraordinary milker, she can easily dispose of even more than is above suggested. In such a case we would increase the bran and oats, rather than the corn.

For the cow disposed to recurring attacks of garget, there must be extra care not to overfeed, and to milk and handle the udder with extreme gentleness. This is all that can be done by way of prevention. If despite this, garget makes its appearance, reduce the feed, and if this does not suffice (as it usually will) give a dose of cow physic, and follow that with a few doses of salt peter—an ounce at a time, two or three times a day, and for three or four days if necessary.

The case of the young cow that does not milk right is not sufficiently described to justify the expression of any opinion. Personally we are very much averse to meddling with teats or udder in a mechanical or surgical way. When anything of this kind is necessary an expert should attend to it.

A MEXICAN RATION.

Please give me a ration from the following feeds: Cotton seed meal, $40 per 1000 kilograms; bran, $45 per 1000 kilograms; corn, $35 per 1000 kilograms with sorghum and Guinea grass grown on the place. Milk retails from 60 cents to $1.00 per gallon.

Tampico, Mexico. J. C. R.

Prices given above for both feed and milk indicate that dairying has not been a popular industry in the vicinity of Tampico and hence we are led to believe that the cows are not of the class specially adapted to dairying. If this should happen to be the fact they should be fed accordingly, for it would be quite foolish to feed a cow, incapable of producing twenty pounds of milk in one day, as we would one that can yield forty pounds.

The best advice we can give in the premises is to suggest mixing two parts each, by weight, of the bran and corn (ground) with one part cotton seed meal and give each cow a daily allowance of from five to ten pounds (or, say, 2½ to 5 kilograms) of the mixture, with what sorghum and Guinea grass they will eat. If both kinds of forage are available at the same time, give them in about equal amounts. It is desirable also that a portion of the forage should be cured as for hay, although we can give no better reason for this than that the cow confined to green forage altogether, seems to have a special craving for something dry. Prof. Sanborn, of New Hampshire, writing to the DAIRYMAN a year or more ago, reported that he had found a little hay equal, pound for pound, to grain for cows on good pasture, and we all know with what avidity cows will follow a load of hay or straw in the pasture.

As we have said above, the daily allowance of grain to these Tampico cows—or, for that matter, to cows anywhere—should be governed by circumstances. If the cow is diverting too much feed to flesh and body fat, the evidence is complete that she is receiving more grain than she can profitably use, more raw material than she can manufacture into milk, provided, always, that the ration contains the proper proportion of digestible protein. There are very few cows that can be brought to their maximum flow of milk on timothy hay and corn meal, because twenty pounds of such hay and ten pounds of corn contain only about 1⅓ pounds digestible protein. It is possible that the maximum grain allowance suggested above may not suffice for some of these Mexican cows. In that event we would take out a pound of the corn and add a pound of cotton seed meal, but not make such a change in one day. Rations should always be increased or changed gradually. We all understand and practice this rule with horses, hogs and steers, but with inexplicable perversity seem to think the milch cow can go from light to heavy feed almost instanter.

FALL PASTURE FOR DAIRY COWS.

I am thinking of sowing a fall pasture for my dairy cows, so as to have something for them to graze upon until late in the season. Was thinking of sowing rye, but hear that it is not good for breeding cattle, that it sometimes causes abortion. J. K.

Enterprise, Miss.

We do not think the specific objection above urged against rye tenable. It is very doubtful if cows ever find sufficient ergot in their feed to induce abortion, unless it may be in certain kinds of mill-feed which contain the sweepings and other foul matter which accumulates about a mill.

It does not follow, however, that rye makes the best fall feed. We think barley or oats better, but in this latitude we can sow winter rye in the fall, pasture it down pretty freely, and harvest a good crop the next spring or early summer.

WEIGHT OF MILK.

Please answer through your paper the legal or generally understood weight of a gallon of milk. W. C. H.

Buffalo, N. Y.

The average weight of a gallon of milk is 8.6 pounds, with small variations above or below according to the quality of milk.

TESTING MILK.

What book would show how to figure out the number of pounds of butter in a certain number of pounds of milk when tested by the Babcock test? H. E. B.

Antwerp, Ohio.

Should advise you to obtain the book on "Testing Milk" by Farrington & Woll. It can be obtained from this office for one dollar, postpaid.

Note and Comment.

Wire Hoops for Silos—Shooking Corn—Fly Repellents—Hydraulic Separators—City Cream Trade.

ED. HOARD'S DAIRYMAN:—On this 7th day of August the silage corn gives signs in this locality of being the smallest crop ever harvested, and on the other hand preparations to build new silos, and inquiries about them and their construction, were never so numerous as this year. It is not only interviews, letters, and lectures, but 'phone calls about them, by the combined scores. Driving into a little village the other day, not far away, three men began their inquiries before our horse was hitched, each planning a silo. The round silo has the "call" in this section, again. Last year it was the square one with rounded corners that led. Evidently this is not a corn year. It was so wet and cold that little corn was planted until after June 15th, and a neighbor is plowing today for corn. Says, "if the September frosts hold off, I can beat the hay crop yet." Corn is spotted, and very uneven, varies all the way from knee high, to as high as the head, a spot a rod square looking very discouraged, and close by is a spot as lusty as a sun flower.

That item about hooping silos with breadths of Page fence, keeps bringing in the inquiries yet, and here is a man who says he is afraid the bottom breadth will give out,—wires pull apart. How can he insure it against this? Well he can simply double a breadth and put the top and bottom of the two together, so to get a big wire on each edge, or he can fold a length over in the middle, making the hoop twenty-six inches wide instead of fifty-two inches, and put on more of them. Not more than two doubled hoops will be needed at the bottom fixed this way, and then use the full width breadths above them. By the way, what is the textile strength of a section of II wire Page fence?

A letter came today, saying they had read in HOARD'S DAIRYMAN about how I shooked up corn in the field, but did not see how, if I only crossed two bundles that I made the other three dozen or so stay in the corners, and to explain. We lay more than two bundles cross wise of each other. We keep crossing them until we have the X as high as our shoulders if we can; reversing tops and butts with both layers of cross bundles, then fill in the corners round and round so to keep the center plumb. That's all there is about it. Bundles that are not tied, lay up pretty well, but you cannot make the X as high, before the corners are built in. We shooked our field of rye that way, and it was a great success, we thought. We have been trying fly repellents, patent, counterfeit, and home made this summer, but in some way the flies do not seem to repel at any of them for any great time, fifteen minutes or so, and we are trying the blanket cure now and it certainly gives a picturesque effect to dairying, to see the cows go afield in their brown tailor made suits, cut Princess pattern, and notice with what unconcern they graze in the pastures, and when they have eaten their fill, lay down in the sun, utilizing their blankets as parasols. Where Burlington burlap blankets are bought in lots, the cost is much below a dollar. Possibly they may not repay their cost in a season, but there is a lot of comfort in them for the cow. The blankets are not proving non-destructible when coming in contact with a wire fence, but the injuries are small, i. e., the holes, and I am in hopes that there will be enough of them left in the fall, to relight the window sash of the barn.

I was greatly pleased the other day to receive a visit from Mason Parmalee, of Michigan, the prize writer of dairy literature, and by the way, one of the high up-to-date dairymen of this country. He has solved the fly and soiling problem, by doubling his silo capacity, and for three years has fed silage the year round and pastured very little, and he thinks it the solution of the dairy problem, as to cow keep. It was of great interest to me to hear him narrate his processes of dairying. This season his store of silage failed him August 1st, and he has to resort to soiling crops, but despite all his skill as a feeder, there was a great shrinkage of milk, with the suspension of silage feeding. It passes his comprehension why the general dairymen will hold onto the summer production of milk, and then feed dry cows through the winter. This is illustrated nicely at our creamery here, which last winter, from November to April 15th, paid $1.10 for milk, and summer milk is a six cent "fluid" through the summer of 1899. Oberlin, O., for years before the war, had the reputation of being a great center for diffusing emancipation ideas, and now a diffusion firm there is proclaiming emancipation from pans, crocks, and high priced whirligigs for separating cream from milk, and by the way they are selling their "aqueduct" separators over the state, there will soon be a great call for water throughout the dairy sections, so much so that the city milk buyer may be enabled to get normal milk again. It is wonderful to hear the happy hydraulic can buyers narrate their experiences, and while none of them think that they are making any more butter than before, it is the great saving of labor in butter making, that compensates for paying rather high prices for big tin pails. The greatest surprise is manifested by the pigs and calves that drink the milk. The sudden generosity of their owners surpasses their comprehension. The half pail of milk is now a generous pail full, and 16 to 1 they can't *feel* the difference, if their eyes do behold the dilution. That farmers have ready money with which to buy these high priced tin pails is evidence that prosperity has reached the dairyman. While they are selling dilution separators, we have a rest on air, lightning, and dynamite cyclone churns; black pepsin butter increasers, steam cheese vats and feed cookers combined, etc. What bug, now that the *hum*bug has been paralyzed and disfigured for life by the kissing bug, will be the next one to sail over the dairyman's "can't fool me" barricade.

The supplying of cream to the cities has so greatly increased, and so many factories are changing from butter and cheese, to supply this cream demand, that it may be said that we have now a distinct dairy industry in northern Ohio. It is so distinct, that prices at cheese and cream factories are not the same. Last winter the cream factories paid thirty cents a hundred more for milk than the cheese factories, and since July 15th, the cream concerns have paid seventy cents, to the others sixty cents, with a wider margin in the not distant future,—so hinted. The amount of cream sent from about here to Pittsburgh and Cleveland is wonderful as compared with three years ago. The small cities are even larger proportionate buyers of cream, and this is having a telling effect upon many a creamery, the shipping of cream, instead of butter making, and the advent of cheaper separators has promoted private cream shipping, and some of the finest creameries in the state have been forced to close doors and sell out, and "for sale—good and sufficient reasons for selling,"—are all too numerous all over the state. The city milk trade is growing all the time, and still there is so much milk offered that it is difficult to see wherein the shipper is any better off than the man who supplies the cream shipping man with milk. In the last case bad debts are unknown, while it is a continual series of losses of all magnitudes, to those who ship to city peddlars.

Ohio. JOHN GOULD.

New York Farm and Dairy Notes.

Renovating Old Pastures.—A Fine Field of Ensilage Corn—The Best Rotation for the Dairy Farm.

ED. HOARD'S DAIRYMAN:—I have recently visited an enterprising dairyman, and on his farm saw a very fine field of ensilage corn. It was then (Aug. 9) about eight feet high. The corn had been planted in rows three feet apart, and the stalks were from six to eight inches apart in the rows. The variety was Early Mastodon, and there was an almost perfect stand of corn over the whole field. It was just beginning to ear, and the dark green color showed that there was plenty of food for it in the soil. As the corn has yet about six weeks in which to grow, I think it will grow to a height of twelve feet or more and mature all the ears and make the very best ensilage.

Your readers will be the most interested in an experiment made in growing this field of corn. A part of the field, the previous year, had grown a crop of grain. The ground was plowed in the fall, and during the winter the manure was applied to it. The remainder of the field had been sod ground which produced a crop of grass the previous year. The manure was drawn during the winter, and spread on the sod. In the spring the ground was plowed, and the corn planted. The part of the field where the corn was planted on the sod turned over in the spring, was producing the better crop of corn. The stalks were larger, and were of a darker green.

The whole field was very promising, but the prospect was there would be a considerable larger growth of corn planted on the sod ground. In my own farming it has been my practice to plow under a clover sod for planting the corn, and in this connection I wish to speak on the value of clover in a rotation of crops.

We have found, on our farm, that the best rotation is corn, oats or spring wheat, and clover. The corn is followed by the oats or wheat, and with these crops the ground is seeded to clover. The clover is mowed for hay one or two years, according to its condition, and the most of the manure is applied as a top dressing to the clover seeding. When the last crop of clover hay has been cut, then we commence to spread the manure, which is drawn from the stable, on the clover sod, and thus prepare the ground for the corn crop which is to follow the next year.

I believe that a crop of corn can be grown on a clover sod in this way, with less than one-half the manure required for growing the same crop in the same kind of soil, which does not contain the clover stubble and roots. Less grain is required with the ensilage to make a balanced ration when good clover hay is fed. I do not think, on land adapted to this kind of farming, that there is anything else that will help to solve the problem of providing a cheaper food for the cows, so a margin of profit can be realized, than this combination of ensilage and clover.

The grain crops mentioned provide food for the teams and for the families, and the straw needed for bedding the cows, — for we must have this to keep the cows clean in the stable, and for an absorbent if we save all the urine. Of course I would grow some oats and peas for the early soiling crop, but the rotation mentioned would be for the main crops which I would grow to feed the cows.

I think I have before written about my plan of ensilage and clover farming, but the results have been so satisfactory on our farm that it is one of the things I like to write about, and there are some things which I believe many farmers need yet to learn, and good things bear frequent repetition. I have supposed that the farmer's soil is adapted to growing corn and clover, and can be easily tilled, and that the general conditions of dairying are similar to those in the locality in which I live. Any plan of farming one can give must be so modified that it can be adapted to the circumstances of the individual.

I have a neighbor who spends a few days early in the fall, in mowing weeds in his pasture, and in reseeding places where it is needed. He has so improved his pasture that it keeps about double the stock that some of his neighbors keep on the same area. The places where but little grass grows are top-dressed with manure, harrowed and grass seed sown on them. I believe the better way for most farmers is to have just sufficient pasture for the cattle, so they will eat it close, and that it should be depended on to furnish feed for the cows only about two months through the best of the season, then it should be supplemented with the early soiling crops. In the pasture there should be as little waste land as possible. I know of pastures where two-thirds of the land is occupied with ferns and weeds. In our plan of intensive farming, we must make the most of the pastures, as well as the cultivated land. W. J.

Corn Stalk Diseases.

(Read before the Nebraska Veterinary Medical Association, February 21, 1899, by A. BOSTROM, D. V. S., Minden, Nebraska.)

I will make an attempt to call your attention to a few facts concerning that inexhaustible subject, corn stalk disease.

The corn stalk is looked upon with suspicion as an agent which sometimes seems to be incompatible with animal life; yet thousands of horses and cattle are turned out to feed upon it every year, and if anything happens to interfere with the natural laws which govern health and life of the animals the corn stalk is held responsible for it; and the question is, What is the matter with the stalks?

Before trying to answer this question, let us consider the corn plant in detail. I believe that the corn plant is subject to the natural laws which govern the vegetable kingdom. We plant the seed, it germinates and grows; we cultivate it, and it gets ripe; we take care of the seeds, and the stalk is left in the field to take care of itself. It is subject to diseases like other members of the vegetable kingdom. Both animal and vegetable parasites may affect its growth; of which the vegetable parasites are the most important group, including such pests as smut, caused by the fungus *Ustilago carbo* and the *Ustilago maydis*; rust, of which the most important is *Puccinia maydis*; and ergot, a fungoid disease not only affecting the rye plant, but many other species of graminae, such as corn, wheat, etc.

About the time of maturity the most tender leaves of the plant begin to fall off upon the ground, and there they become covered with small fungi of the genus *Penicellium*, *Aspergillus*, *Mucor*, *Ascophora*, etc. Small sideshoots, developing only rudimentary ears, die early, and in going through the process of decay contain innumerable numbers of the above named fungi. Now, this is the actual condition of the corn plant, as near as I can describe it.

Burrill, Billings, and other, say that they have discovered a germ that is the cause of the corn stalk disease. Others say the corn stalk contains so much saltpetre when grown in certain places, that the animals eating it die of saltpetre poisoning.

Now, after considering the various conditions of the corn plant, let us turn our attention to some of the other plants for comparison.

Clover is subject to the attacks of several fungi, of which the most important is the *Peronosdora tribolium*, which exerts its irritating action directly upon the gastro-intestinal mucous membrane, or the formation of a toxic substance which, acting particularly upon the liver and the brain, causes what is

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,
67 Main Street, - Cortland, N. Y.

known as clover-disease. Straw of wheat and oats, when damp and going through a mouldy change, is affected by various fungi, such as *Tilletia, Caries, Puccinia, Graminis*, etc., causing derangement of the intestinal and urinary organs, followed by paralysis and death.

We have already seen that the corn stalks are sometimes affected by various fungi, and I am inclined to believe that if the fungi on clover, produce clover- disease, the fungi on corn stalks are the cause of the so-called corn stalk disease. I have seen both horses and cattle die from eating straw covered with fungi. I have seen hogs die from the effect of mouldy flour. I have had considerable experience with the so-called cerebritis or encephalitis, described in our veterinary publications as being caused by wormy and mouldy corn, and I believe that all these conditions, the corn stalk disease included, are cases of fungus poisoning.

Corn stalks may be the cause of other conditions which frequently result in death. Sometimes corn stalks are cut up and fed to cattle and horses in July and August, when grass in the pasture is in sufficient, and when fed fresh and in limited amounts I have never seen or heard of any bad results therefrom; but when the stalks have been cut at this time of the year and allowed to remain in the field for a week or ten days—long enough to allow the development of an active process of fermentation—and then fed, I have seen the most serious disease, with death following in one-half to two hours of *acute tympanitis or meteorism*. If seen in time the animal can be relieved by tapping. After the escape of the gas the animal gets well in a very short time. I do not believe that any other germ, except the bacteria of fermentation, could be the cause of the production of gas.

THE COST OF CERTAIN GRAIN CROPS IN WISCONSIN.

The forthcoming annual report of the Wisconsin Labor Commissioner, Halford Erickson, will lay before the public some very valuable data. On the question of agriculture and the cost of production of crops, Mr. Erickson has taken especial pains to get as near the actual truth as he possibly could.

He has obtained full returns from 410 of the most intelligent and successful farmers in the state, covering a period of six years, and from them has deduced the following figures relating to the cost of producing the crops named:

"The expense of seed, taxes, depreciation of land, labor, machinery and horses used, feed and incidental outlays, amounted to $6.12 per acre for one crop of wheat, and $7.91 per acre for one crop of corn.

To the average yield the past six years this is equivalent to about thirty-five cents per bushel for wheat and sixteen cents per bushel for corn. If to this is added interest at six per cent on the value per acre of the machinery and horses used, the annual investment and the value of the land as estimated or given by the farmers, the expenses for wheat would be increased from $6.12 to $9.45 per acre, or from thirty-five to fifty-four cents per bushel and for corn from $7.91 to $11.36 per acre, or from sixteen to twenty-seven cents per bushel.

During the six year period, the average price per bushel for these crops in the local markets or elevators, was sixty-one cents per bushel for wheat and thirty-four cents per bushel for corn. When to this is added, in each case, the value of the by-products at the amount placed upon them by the farmers themselves, the value per bushel is increased to sixty-eight cents for wheat and forty-one cents for corn. The cost and value, respectively, was thus fifty-four and sixty-eight cents per bushel, in the case of wheat and twenty-seven and forty cents per bushel, in the case of corn. This is equivalent to a surplus, or profit, of fourteen cents per bushel in the former and thirteen cents per bushel in the latter case. As said above, these are the results of 400 selected returns. But as the yield in these cases was considerably larger than the average yield for the state, it also follows that the surpluses here shown are higher than the average profit of these products. This is also shown by the final results as obtained from over 1,500 returns. These returns were picked out from the total number received, nearly 4,000, because they were found to fairly represent all classes of farmers int he grain growing portions of the state and show a smaller yield per acre, and hence a higher cost and lower surplus per bushel than that given above. The average profit or surplus, as computed from the results of all returns, ranged from five to twelve per cent on the capital invested or used.

PROPORTION OF EXPENSE ELEMENTS.

As to the proportion of the various elements of expense, to the total expense, the following results were arrived at: The expense of labor was 22.28% of the total for wheat and 44.45% of the total expense for corn; of seed, 12.27% for wheat and only a fraction of 1% for corn; of depreciation of land, machinery, horses and incidental outlays 27.63% for wheat and 22.95% for corn; of taxes, 2.72% for wheat and 2.26% for corn; of interest on the value of machinery and horses used, and on the amount of the annual investment, 7.26% for wheat and 7.05% for corn; of interest of the value of land, or rent, 27.84% for wheat and 23.24% for corn. The proportions given here for wheat apply also, with but small variations, to oats, rye and barley, raised on the same land and under the same conditions.

This investigation was made on a basis sufficiently broad to cover the ground fully. The inquiries were carefully prepared and returns edited in every case. The results at every stage were submitted to leading farmers and experts and their suggestions adopted. Every precaution was taken to avoid errors throughout the whole work and therefore the results were reliable and may be safely used. As to the conditions on the farm the result is that during the six years, or the period covered, the farmers have on the average done as well financially in proportion to the amount of their investment, as those engaged in most other industries."

PATRON'S WORK OUTLINED.

Things a Butter Maker May Expect.

In this short paper read before the Indiana dairymen by Herbert Newby, the writer shows how the patron must co-operate with the butter maker if good butter is to result:

In writing this paper, I know I have taken up one of the greatest subjects which confront the creamery men of to-day. It is one of the problems which comes up for discussion among both the factory men and also the patrons. As all the creameries are co-operative, in fact whether in form or not, then success must depend upon the thoroughness of the co-operation of all parties concerned, and how to secure this to the greatest extent is the question. Co-operation means all parties concerned working together to accomplish some definite result.

In the first place, the butter maker must be a man who can gain and hold the respect of his patrons, and to do this his very word must be as good as his bond. He must work, and make his patrons feel that he is working for their good, and that he is watching after their interests in every way.

The best butter can only be made from the best milk, so the butter maker has the right and must expect his patron to furnish him with the very best raw material (i. e., milk). By this I mean milk from good, healthy cows, which have had proper care, fed with good, wholesome feed, milked in a clean place, free from filth and foul odors. After the milk has been carefully drawn from the cow in a clean, sweet pail, it should at once be thoroughly strained and cooled, or better still, also aerated.

Then comes the question how to deliver the milk at the factory in the very best condition, with all the fine flavor produced by nature retained, and with no artificial flavor added. One good way to do this is to have a good clean cover of some kind to place over the cans, and in winter it should be sufficient to keep the milk from freezing; then be sure your milk is at the factory on time. The butter maker need not expect any thing of his patrons which he himself is not willing to do, so if he leaves things dirty and greasy, he may expect them to do the same way, and also to furnish him with poor milk; but if he is careful in every detail regarding cleanliness in his work, then he may expect his patrons to keep all their cans and other milk utensils sweet and clean, and to do this the utmost care and vigilance must be exercised. The cans are especially liable to become dirty and in bad shape unless they are carefully washed and scalded each time after using them, and plenty of good, bright sunshine will not hurt milk vessels in the least.

Too many persons seem to think a butter maker should be able to take any and all kinds of milk and work it up into the finest product. He cannot do this. But furnish him with good milk, then hold him responsible.

We sometimes hear of a man being prosecuted for adulterating his milk with a little pure water, or taking out some of the butter fat, but I would rather (as the Babcock test would catch him) see a man prosecuted for adulterating his milk with filth, which no doubt his farm needs, for filth and dirt are the causes of more bad butter than anything else.

Some one may ask why the need of each patron being urged to take such good care of his milk? We would answer, milk from an unhealthy cow is not fit food for a human being. If impregnated with filth, it is liable to have in it the germs of disease; if it comes in contact with foul odors or is allowed to sour, it gives the undesirable bacteria a big start, which cannot be overcome.

Every patron should constantly keep in mind the fact that the price he receives for his milk depends on the price the butter maker gets for his butter, and this in a large measure depends on the condition the milk is in when it reaches the hands of the butter maker.—*Dairy Reporter.*

Oleo Notes.

Some capitalists are said to be building a large oleo factory in Pennsylvania, with the expectation that a profitable crevice can be found in the new law that will let them sell the stuff colored like butter. The scheme seems to be to secure the coloring in some occult and unnamed way that shall elude the analysis of the chemists, and thus quibble past the law. But they will be apt to run against snags, especially if the hoped-for enactment at Washington is secured.

The Chicago oleomargarine output for the month of June, 1899, exceeded that for the same month in 1898 by about 20,000 50-pound tubs, the number of tubs sent out this year being 45,706. The output for the year ending June 30, 1899, exceeded that of any other year since 1894 by about 130,000 50-pound tubs. It is to be hoped that when the new commissioner in that state gets fully into harness that this sort of thing will be checked. If the production is not directly affected, the sale in that state ought to be.—*Dairy Reporter.*

The Belle Meade, Tennessee, Dairy Farm.

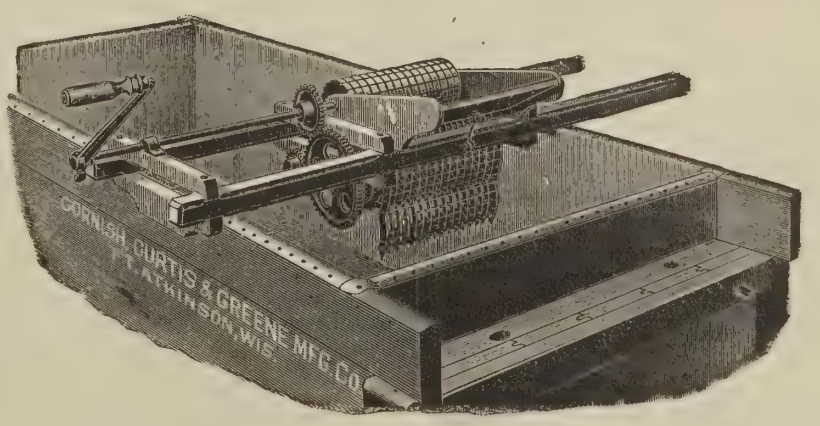
The Nashville, Tennessee, *American* gives the following readable description of the famous Belle Meade dairy building and herd of Jersey cattle. It says:

The Belle Meade dairy, with its hundred or more cows, with its splendidly arranged barn, and with its modern equipment of dairy machinery for the manufacture of its products, ranks easily the finest and most complete in the south.

The average of the herd, from a dairy standpoint, is high, and many of the cows are representives of the finest of those strains, for which this section of Tennessee has long been famous. The barn is built around four sides of a hollow square, inclosing an open court, to which the cows are admitted by a passage way, and from which they enter through convenient doors and pass to their proper places. The work of feeding has been reduced to the simplest and most economical system. The large silos and bran rooms are situated in one corner of the barn, and a feed car passes on a tramway in front of every stall. The floor of the aisles is made of solid stone, and is kept most remarkably clean.

The skimming room is situated in one corner of the court, and its equipment, which has just been installed, is most complete and elegant, having been built especially for the Belle Meade farm, by P. M. Sharples, of Westchester, Pennsylvania. The vats are handsomely finished in natural wood, and the separator is of the most improved Sharples tubular pattern, having a capacity of 2,500 pounds of milk per hour, and producing the finest quality of cream. By using this centrifugal system of separating the cream from the warm, fresh milk, not only is butter produced in much larger quantities, but is of a greatly superior quality.

It is quite a pleasant sight to the visitor to see this large herd of Jerseys, as it comes in from the pasture for the afternoon milking. With an accuracy that is astonishing, each cow finds her proper place in the long lines of stalls, and when all are in, and are quietly eating their evening meal, the milkers begin their work. Perfect silence reigns, except for the quaint old southern melodies that the darkies sing to their cows, just as the milkmaids of Switzerland are said to do.



As is well known to every good dairyman, music hath charms not only to soothe the savage breast, but also to keep a dairy cow in good humor, and, passing down the long lines at Belle Meade, the patter of the streams in the buckets may be heard, keeping time to the plaintive chanting of the old darkey as he hums his soothing southern songs.

Great economy of labor and time is exercised in handling the milk. From the buckets of the milkers it is poured into a conductor, which projects through the wall from the cow sheds into the skimming room and empties into the receiving vat, thus rendering it unnecessary for the milkers to enter the skimming room. Passing from this vat into the separator, the cream is extracted and flows into large cans, while the skim milk flows from the separator to the skim milk vat. Another conductor leads the skim milk back into the cow shed, where it is drawn out through a "perfection" gate and fed to the calves.

The cream is then placed on a little cart and removed to the dairy house, which is a separate department, complete in itself, and is in charge of an experienced butter maker. The building is a very handsome stone structure, and is most admirably adapted to its purpose. In one end of the cream room is an oblong stone basin, through which a stream of cold water is constantly flowing, by means of a siphon, from a well near by. Into this room the cream is taken direct from the separator, and after being thoroughly cooled and aerated on a "Star" aerator, is set away in cooling cans to ripen for churning.

Under such conditions, it is not to be wondered at that the product from this dairy should take the very first rank in general excellence. Old methods will not do for these new times, and the day is not far distant when the Southern dairyman will realize more fully than he has yet done that in order to get the best results and the largest profits from his work, he must adopt the modern methods and improved appliances and machinery.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentation to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, **$25.00**

Silo Experience.

ED. HOARD'S DAIRYMAN:—I built and fitted my first stave silo four years ago. It has been filled and fed out four times and given satisfaction every winter. I have three just alike and I would not build any other kind, for the stave silo is cheaper than any other, easier and quicker built and the loss from spoilt silage is less than any other kind, and I believe will outlast any other kind made of wood.

I will give my plan for building, and have found it cheap and convenient and certainly effici ent. First, lay off a circle on the level ground the diameter wanted, dig a pit eight feet deep. If the ground is clay it need not be walled up, but lay two courses of brick around the top to protect the edge of the earth wall from crumbling and to make a foundation on which to set the staves; lay the brick in cement mortar, having the foundation eight inches wide and two brick thick, to keep the lower end of the staves dry; use 2×4 pine or hemlock, twelve, fourteen or sixteen feet long, making the total depth twenty, twenty-two or twenty-four feet, and walls two inches thick. I think it much better to use 2×4 just as it comes from the saw and the circumference is broken so often that the inside edges coming together make a much better joint than if wider lumber were used, and if there are any of the pieces of timber sprung, it can be drawn together much better by the hoops. Before beginning to set up the staves I put four posts in the ground a little higher than the staves, on which to build my roof, and use these posts as scaffolding. When posts are up and fastened with the plates at the top—out just a little, larger than the outside circumference of the tub would be—stand up the first stave and after plumbing, so as to get it perpendicular both ways, the lower end resting on the brick foundation, back an inch or two from the inner edge of the brick and the top end nailed to the plate.

On this first stave nail with small nails, on the inside at both top and bottom, an old barrel stave, set up the next pieces of timber to the right or left and nail through the barrel stave, and so on, using the old staves as needed, until at last the shell or tub is set up and held in place by the two rows of old staves at top and bottom, making complete hoops on inside.

The top of tub can be stayed temporarily to the scaffolding at the top to secure from wind. After all is closed together, put on the iron hoops and draw together, knocking off the inside hoop of staves as soon as the iron hoops are sufficiently tight.

The iron hoops are made of two or three sections of five-eighths round iron, with screws and taps on each end, put through 4×4 pieces of hard wood, so as to pull from opposite directions. Cut the blocks of wood long enough to use for two sets of hoops, so each one will stay the other. The hoop can be in two or three sections, to suit circumference of silo.

Any one handy with tools can put it up quickly and with but little trouble, and when empty the walls quickly dry out and that makes it the most lasting silo. By having part in ground and part above ground, not so much elevating power is needed in filling, and if built outside of cow house, but close enough to place the cutter on the floor over head, the corn can be unloaded from wagons to platform on level with floor to feed the cutting machine, and by this save ten or twelve feet of elevator and necessary power to run it.

In finishing up the silo, after the hoops are drawn as tight as possible, saw out the doors between the hoops; two doors cut in the side, one near the ground and the other five or six feet above, are sufficient for feeding out the silage.

Saw the doors out twenty-four inches wide and twenty-eight inches high; saw with a bevel to fit from inside, so that when in place and filled the pressure of silage holds in place. I cover over each door on inside when ready to fill, with a square piece of tarred paper to exclude the air, and also in finishing up on the inside, fill up any openings there are where the staves join the brick foundation, with cement mortar, and also cement down on the clay wall about eighteen inches to exclude the surface water and rats.

It is not at all necessary to wall or cement the earth wall if it is clay. The silage keeps well against the clay, both sides and bottom. This is the poor man's silo because of its cheapness and will do for the rich man also as there are none other that will show better silage or less waste or rotten silage.

A silo built this way, twelve feet in diameter and twenty-four feet deep, will hold a little over fifty tons and can be put up ready for use here with good pine lumber, for less than fifty dollars. A safe estimate with lumber $1.50 per hundred feet and rod iron at $2.00 per hundred pounds, would be one dollar per ton of silage.

I feel now after four years' experience that if I had to tear down the silo every year to get out the contents like opening an oyster can and throwing it away, that each year it would pay me to build anew, but on the contrary after four years' use, I see no sign of decay of timber.

I see no reason to think a silo of this kind will not give good service for twenty years. My silos are painted outside with cheap mineral paint and have a plain clapboard roof.

I have used corn, sorghum, cow peas, soja beans in the silo. My first choice is well eared field corn put into silo, cut up to half inch lengths when well dented, when some of the outside shucks begin to turn yellow. Next choice is sorghum allowed to ripen the seed well. Do not like the cow pea or soja bean unless mixed in throughout with the corn or sorghum. I have three stave silos in use, and do not see how I could run a dairy without them. J. N. MERONEY.

Maury Co, Tenn.

Shredded Silage.

ED. HOARD'S DAIRYMAN:—Judging from statements which appear from time to time in print, there seems to be some diversity of opinion in regard to the advantages of shredding ensilage as compared with its preparation in the old fashioned way with a square cut machine.

In my own case, however, the results of the experience of the past three years, during which I have used the shredder exclusively in filling my silo, have been such as to thoroughly remove from my mind all doubt as to the superiority of this method of preparation. Before deciding to experiment with the new method, I investigated the subject with considerable care, and found that chief among the points of advantage claimed by those who had used the shredder for this work, were (1) Closer packing in silo, whereby the air was more effectually excluded; (2) A more fibrous texture enabling the product to be conveniently handled with a pitchfork; (3) The removal of the liability of producing sore mouths in the cattle fed from the contents of the silo, caused by the sharp edges of the chopped pieces; and in my own experience all these results have been fully realized. The closer packing of the ensilage produced in this manner amounts to a saving of at least 20% in the space occupied in the silo.

I filled my first silo in August, 1896, with a shredder which I purchased of the St. Albans Foundry Co., and operated it with one of their Internal-Double-Geared Three-Horse Tread Powers. The shredder was fitted with interchageable rolls; that is, it is so constructed that the upper roll can be readily removed at will, and one of large or small diameter inserted, according to the nature of the work to be done. With the large roll, the entire plant, ears and all, passes through and is shredded up, while with the small roll, the ears are pinched off and only the stalks and leaves are shredded.

My silo is 15×18 feet and 40 feet deep. This we filled full and besides ran several tons onto the bay, which made excellent fodder.

Part of the time that year I used the snapping rolls and part of the time the big feed rolls. The following year, however, I used the big feed rolls exclusively and put all of the corn into the silo and have since adhered to this plan, as I believe this is the most economical way to treat it.

The contents of my silo have been frequently inspected by good judges of ensilage and invariably pronounced to be the best that they have ever seen. Every particle of it keeps perfectly. We filled the silo with my regular farm help. The year before I bought the shredder, I paid for husking corn $80, and for grinding $75, which I now believe is saved by the silo and shredder, as I make more butter, buy less grain and my cows look better than ever before.

It was claimed by some that my shredder would be rather slow in comparison with a square cut machine, but we run through twenty-three two horse loads in one day (one load in nine minutes) snapping and husking the ears, which was much quicker than we could husk the corn by hand, to say nothing of the shredding.

This record was made with the snapping rolls in the machine. After we substituted the larger roll, we did still more rapid work, though I have not at hand the exact figures to show the exact amount of this work.

I have been feeding all of the past year from my silo and the ensilage is sweet and good throughout. I certainly intend to stick to the shredder for filling my silo until some still better method is discovered, and would not think of going back to the old plan of cutting the ensilage. H. W. STRONG.

Washington Co., Vt.

Feeding the Brood Sow.

(From a paper on the "Bacon Hog Industry," prepared for the Nova Scotia Pork Packing Co., by J. J. FERGUSON, B. S. A., Smith's Falls, Ont.

After the sow is separated from her spring litter, she will be able to find a living upon good grass or clover pasture, with little or no additional grain ration. Two or three weeks before she is due to farrow her fall litter, her ration of meal should be increased. We have found a mixture of bran and shorts, equal parts, about the best at this time. The sow should not be made over fat by heavy feeding, but a thin condition often results in weak, puny pigs at farrowing time. After the fall litter is weaned, the sow can be very cheaply carried through the winter upon a ration of mangels or sugar beets. Of these we feed about thirty pounds per head per day, in two feeds, morning and night, with two or three pounds of whole oats fed at noon. Turnips can be used, but to get the best results they should be sliced or pulped; our mangolds are fed whole, which is quite a saving in time and labor. Not only is this ration cheap and convenient to feed, but it carries the sows along in first-class breeding condition. This, combined with exercise taken at will in roomy yards, results in a much smaller loss of young pigs, when farrowing time comes, than is usually found where sows are kept closely confined during the winter and fed entirely upon a grain ration.

A month or so before farrowing, the sow should receive a lighter ration of roots and more meal. Large quantities of cold, watery roots, fed shortly before the birth of the pigs may give them such a chill as to result in their death. Roots do not contain sufficient mineral matter to build up a proper bony framework in the litter. The sow should farrow in a warm, dry pen, to which she has become accustomed for some time. A fender should be placed around the base of the walls, projecting out at the foot, and ten inches from the floor, to prevent her over-lying any of the young pigs. For the first week after farrowing she should be fed but a light meal ration of bran and shorts, or bran and finely ground oats mixed to a thin slop with warm milk or skim milk.

Over-feeding of the sow at this period, or feeding her heavily on barley, or pea-meal, is very likely to cause a milk fever, often resulting in the loss of dam and litter. Her ration during the time she is suckling her litter should consist largely of bran, since this is one of the very best milk-producing foods obtainable. When the young pigs are two weeks old, they should be provided with a supply of new milk in a shallow trough or pan, protected from the old sow. After a time, skim milk may be substituted, with the addition of a small quantity of ground oil-cake, shorts, or oat-meal. When treated in this way they become well able to do for themselves at seven or eight weeks old, and will suffer no set back when taken from the mother.

It is a serious mistake to wean pigs at four or five weeks, as is so often done, resulting in their making slow growth during the second month. Every day of lost time on the pig's part means money lost for the owner; they must be kept moving right along steadily from start to finish. The sow and litter should have access to a roomy yard, or, if she farrow in late spring, to a small clover or grass patch. When the pigs are ten or twelve weeks old they will make good use of pasture of this kind; in many sections of Ontario the farmers carry their hogs, during the summer months almost entirely on clover.

Light, movable fences or hurdles are made use of to confine the hogs to a portion of the field. When this is pastured off, the hurdles and hogs are moved to a fresh piece. This seems to give better results than allowing the hogs to roam over a large area. In every case, the hogs should have two or three copper rings inserted in their snouts to prevent their changing the face of nature; these will do it effectually. A hundred of them and a pair of pincers for inserting them, can be bought for twenty cents. It is well to provide a light shelter of boards to protect the pigs from sun and rain.

While pigs will grow and gain on clover alone, it is always advisable to give them a light grain ration in addition, one-half or one-third of the amount they would receive if fed on grain alone. Hogs finished on clover alone seem to yield a larger number of soft bacon sides than those properly finished on a grain ration, so that care must be exercised not to run to an extreme in this matter. Hogs on clover pasture should have a plentiful supply of clean water available at all times. If skim milk can be supplied them, at the rate of six or eight pounds per head per day, it will be found of great advantage. About a month before the hogs are to be marketed the finishing feeding should commence. This is not to be taken to mean fattening, but rather a firming up or ripening. Much has been said as to the injurious effects of certain feeds in the production of soft bacon. Of this we are satisfied, with the right hogs good bacon can be produced with greatest certainty by feeding a mixture of the different grains commonly grown upon our farms. No hard and fast rule can be laid down as to what grains to feed, as this matter will be regulated largely by current market prices, and also by the quantities of each which can be grown in each locality. A mixture of oats, peas and barley, seeded at the rate of one bushel of each per acre, will not only give a larger yield than any of these sown separately, but will be found to furnish a first-class grain ration for finishing hogs. An exclusive diet of any one grain will not give as good results. We now know that corn can be fed to finishing hogs without injury, if they have been fed on a good bone and muscle forming ration earlier in life, and do not at any time receive more than, at most, one-half of their meal ration of it. In all cases it is better to keep the hogs' appetite sharp; he should not have meal food lying almost constantly in his trough.—*Farming.*

MR. R. G. WELFORD, in an address before the Illinois Dairymen's Association, made the following observation upon the beneficial effects of dairying on any community in which it exists. He said:

"In my experience of thirty years in Illinois, Wisconsin, Iowa and Missouri, I have noticed that wherever the dairy cow is there is prosperity, whether the climate be good or bad. Dairying has also greatly increased the sociability and contact of farmers with one another, for they meet when they come to the creamery or factory. While they are waiting they discuss how to get and keep good cows. This has done wonders for such farmers. It has also called out more intelligent farming and we find that the papers that cater to their ideals are sought for and eagerly read."

SOUTH DAKOTA STATE FAIR MILKING TEST.

At the South Dakota State Fair, the management have provided for a trial of milch cows under the following provisions:

CLASS NO. 34—MILKING BREEDS.

83 Cow producing milk from which most butter is made.....$25 $15 $10

Parties making entries in the milk test shall notify the Superintendent ten days before the opening of the Fair, that arrangements may be made for each cow entered. Box stalls will be furnished each cow entered. Cows to be under the direct supervision of officers of the Agricultural Society or their agent. Name, age, breed, date of last calving, kind and quantity of feed used, must be furnished the committee. Owners will be permitted to feed, water and milk their own cows. The test shall be made in public with the Babcock test.

It naturally follows that the man who is making one hundred per cent net profit selling milk preservatives, is absolutely sure that they are harmless, but that is no reason why we, who have to be dosed with the stuff, should allow him to be the judge of the matter. The compounds he puts up may act in different ways on our stomachs and his pocket book, and we are much afraid that the stomach will get the worst of the transaction.

Our Special Elgin Letter.

Ed. Hoard's Dairyman:—On the Elgin Board of Trade, Monday, three lots of butter were offered, and 20¾ cents was bid on all. Union and Garden Prairie declined to sell, but Dundee sold its offering of 2,400 pounds at this figure. The Quotation Committee declared the market firm at 20 cents. The sales of the past week aggregated 660,000 pounds. The markets for the corresponding week of the three preceding years were as follows:

Aug. 15, '98, 9,900 lbs. of butter sold at 18⅛c,
Aug. 16, '97, 5,160 lbs. of butter sold at 16⅛@16¼c.
Aug. 17, '96, 21,660 lbs. of butter sold at 17c.

The New York market on Monday, was reported firm at 20 cents.

The dairymen of Elgin, Dundee and Algonquin townships, or those who are patrons of the three condensing factories, at these respective places, have held meetings during the past week, and perfected plans for an organization, the object of which is to secure better prices for their milk.

They consider that the dairyman receives too little for his product and pays too much for feed and stock to make the business a paying one, and it is in the hope of bringing about a satisfactory adjustment that these meetings have been held. The farmers all seem to favor a permanent organization of all those residing in the territory from which the milk supply comes.

An association was formed here on Friday, at a meeting called for that purpose. S. N. Wright was chairman, and D. W. Wilson, secretary.

Mr. Wright explained that the object was to arrange to act in unison with the dairymen who had held meetings in other towns, in an effort to get a better price for milk.

Judge S. Wilcox made an address giving the cost of producing milk during the last few years and the price which had been obtained for it. He showed that the returns were not what they should have been all the time. In order to have a better understanding and to arrange matters so that a systematic effort be made, he moved that an organization to be known as the Fox River Dairymen's Association be formed, which should be permanent and have for its object the promotion of the interests of the dairy farmer. It would be in fact a renewal of an organization which was in existence several years ago. S. N. Wright, President; George Busche, Vice-President; D. W. Wilson, Secretary; Clarence Bishop, Treasurer; S. Wilcox, F. L. Shepherd and J. Mason, Directors.

The Dundee and Algonquin dairymen held a joint meeting on Monday and decided to unite with the organization formed here.

Elgin, Ill., August 14th. H. C. B.

DAIRY MARKETS.

ELGIN, Ill., Aug. 14—Ninety tubs were offered, 40 sold at 23¼c; committee reported firm at 20c.

CHICAGO, Ill., Aug. 14—Butter—Creamery extra, 19½c firsts, 17½@18c; seconds 15@16c; dairies, selections, 17c; No. 1, 14c; No. 2, 18c; extra ladles, 13½@14c.

Eggs—Fresh, at mark, cases returned, sold at 10½@11c; loss off, cases returned, 12½c.

Cheese—Full cream, Twins, new, good to choice 9¼@9½c; Young Americas, 9¾@10c; Swiss, 8@10¼c; Limburger, 7@8½c; bricks, 8@9c.

Bran—Firm at $10.75@11 per ton.

Shorts—Quiet and sold at $12 per ton.

Cattle—All desirable grades of beef cattle met with a good demand, and prices ruled steady to 10c higher, with a load of 1,490-lb beeves at $6.45 or 25c above last week's top, 15c above the previous highest price this year, and the highest since 1896. A load averaging 1,448 lbs. sold at $6.35, with 1,210-lb steers at $6.10, and 1,326-lb Westerns at $6.10. Most of the native steers sold at $5.50@6.10; some 1,278-lb stillers sold at $5.80. Very few native steers sold below $5. About 900 grass Westerns were received and prices ruled strong with some 1,352-lb grassers at $5.40, the highest grass rangers in many years. A lot of 460 Western heifers averaging 1,073 lbs sold at $4.75. Texas cattle nominally unchanged, Native butcher stock ruled steady, and canning stock was reported firm.

MILWAUKEE, Wis., Aug. 14—Butter—Creamery—Fancy prints, 19½c; extras, 19@19½c; firsts, 17@18c; seconds 16@17c; imitations, 16@17c. Dairy—Selections 15@17c; lines, 13@15c. Market strong and 1c higher, all kinds being scarce and wanted; receipts 8,400 lbs.

Cheese—American full cream—New, choice to fancy, 9@9⅝c. Brick—New, choice 8½@9c. Limburger—New, choice, 8@8½c. Swiss—Drum, choice 12½@13c; new block, choice 10@10½c.

Eggs—Fresh, per doz 11½@12c, loss off, cases returned.

MUSCODA, Wis., Aug. 14—Offerings to-day, 1,100 boxes Twins, 9@9½c; 90 boxes Daisies, 9⅜c.

FOND DU LAC, Wis., Aug. 14—Offerings 618 Twins; market easy at 9 cents.

PLYMOUTH, Wis., Aug. 8—Sales to-day 1,025 Twins at 9¼c, 975 Young Americas at 9¾c.

SHEBOYGAN FALLS, Wis., Aug. 9—Sixteen factories offered 1,188 boxes of cheese on the Call Board to-day, and though the market was quiet and bidding slow, all were sold as follows: 636 cases Young Americas, at 9½c; 212 Twins, at 9⅝c and 340 Daisies at 9½c.

MANITOWOC, Wis., Aug. 9—Offerings at Dairy Board of Trade to-day were 800 boxes Daisies, 135 boxes Twins, 850 boxes Young Americas. Sales, 500 boxes Daisies at 9¾c, 200 at 9⅝c. All offerings Twins at 9¼c, and Young Americas at 9½c.

PHILADELPHIA, Pa., Aug. 14—Butter—Separator creamery extra, 19½@20c; creamery firsts, 18½@19c; seconds, 16@17c; imitation creamery, extra, 16c; firsts, 15c; seconds, 13c; ladle packed extra, 14@14½c: firsts, 13½c; seconds, 13c. Print butter, creamery extra, 22c; firsts, 21c; seconds, 18@19c.

Eggs—Pennsylvania and nearby, 15c; western, 15c; southwestern, 14c; southern, 12@13c.

BALTIMORE, Md., Aug. 14—Butter—Market strong; creamery separator extras, 20@21c; extra firsts, 19@20c; creamery first, 18@19c; creamery, imitation extra, 16@17c; ladle extra, 16c; western store-packed, 12½@15c.

Eggs—Market firm; strictly fresh stock, 13@13½c.

KANSAS CITY, Mo., Aug. 14—Butter—Creamery, 17½c; dairy, 14c.

Eggs—Fresh, 10c.

ST. LOUIS, Mo., Aug. 14—Butter—Steady; creamery, 16@19c; dairy, 13@16c.

Eggs—Firm, 10½c.

CINCINNATI, O., Aug. 14—Butter—Firm.

Cheese—Firm; good to prime Ohio Flat, 9c.

Eggs—Firmer; 9½c.

NEW YORK, Aug. 14—Butter—Creamery, extras, 19½c; firsts, 18½@19c; state extras, 19½c; firsts, 18½c.

Cheese—State full cream, large or small colored or white, choice, 9¼@9½c.

Eggs—State, Pennsylvania and western, 16@17c.

NEW YORK MARKET.

NEW YORK, Aug. 12—Butter—Receipts for the week, 37,180 packages. Exports for the week, 13,026 packages.

Exports continue to go forward freely and the market is ready and cheerful under the stimulus of foreign buying.

There has been better all around trading the past week, with much lighter receipts and market closes steady on all grades and shows increasing firmness on fancy goods. Local and out of town buyers bought liberally of extra fresh creameries at 19@19½c and we note sales to exporters of lines good to fine ones at 18@19c, and lines of fair to good ladle goods at 13@14c.

Creamery, extra, 19½c; medium, 18@19c; poor, 14@16c. Dairy, extra, 18@18½c; medium, 16@17c; poor, 13@15c.

Cheese—Receipts for the week, 34,135 boxes. Exports for the week, 11,363 boxes.

The market is steady with a firm undertone to prices; trade this week, however, was light at last week's rates. Sales are reported from the interior of the state at 9¾@10c. We quote:

Full cream, small, extra, 9¾c; medium, 9@9½c; poor, 7@8c; large, extra, 9½c; medium, 9@9¼c; poor, 7@8c.

Eggs—Rec ipts for the week, 41,095 cases.

Strictly fresh gathered eggs are in light supply and sell readily at full prices. Other qualities are plentiful and irregular in prices. We quote:

N. Y. State & Pennsylvania, per dozen, 15½@16½c; western and northern, best marks, 15@15½c; other sections, 12½@14½c.

David W. Lewis & Co.
177 Chambers St.

BALTIMORE MARKET.

BALTIMORE, Aug. 10.—Butter—The past week has been about as uneventful in this line of business as any of its predecessors this season. Ordinarily, we would not note the incident, because every summer is presumed to develope a tired spot; but just now, with exceptionally cool weather, which has continued an unusually long time, to wit: several days, one would suppose that there would be a sallying forth of local buyers to replenish their holdings that had yielded to the demands made upon them during the excessive heat of the early dog days, also an influx of traders from nearby cities and towns, with the same laudable purpose in view; but the fact is, that the local talent remain in hiding, or have not dared to venture back in active resumption of business along the old lines, and the flood of strangers, sweeping along our streets, are here for their recreation, and with one accord and great unanimity, have refrained from visiting the wholesale districts, confining their efforts to the purchase of twenty cent articles marked up to twenty-nine, of which they seem never to tire until they arrive home and display their purchases to the merciless criticism of those unfortunates who could not accompany them on their raid. And yet the receipts of separator creamery and gathered cream ditto, which have been of the usual quantity, respectively, have by a large majority, gone their several ways, and have been absorbed with as little effort as effect; no one seems anxious for anything, and when they get it, not a ripple appears on the calm surface to mark when or how it was done. The *entente cordiale* of buyer and seller lies down with *laissez faire* of the market, and they need no leader—it is just a condition of "is." Receipts of other varieties, including store-packed, are light, and though grading low, are nearly all sold on arrival.

Creamery Separator, extras 19c; firsts 18c; seconds 17c; gathered Cream extras 17@18c; firsts 17c; seconds 16c; Ohio, extras 17@18; firsts 17c; seconds 16c; Iowa & N W. Ladle, extras 14c; firsts 13c; seconds 12c; Ohio & Indiana Ladle, extrrs 14c; firsts 13c; seconds 12c; Ohio Storepacked, extras 12½@13c; firsts 12c; W. Va. extras 12½@13c; firsts 12c; Creamery blocks (2lb), extras 21c; firsts 20c; seconds 19c; prints, (½lb), extras 21c; firsts 20c; seconds 19c; Md., Va. & Penna. prints, extras 19c; firsts 18c; seconds 16@17c.

Eggs—Under continued light receipts of all choice fresh eggs, and active demand, we write our market firm at thirteen cents. Note—Please bear in mind that our quotations are for choice fresh eggs; all faulty stock has to be sold on their merits.

Cheese—Receipts of cheese continue light; the demand is fair; market firm.

New York state, Cheddars, fine 9¾c; choice 9¼@9½c; fair 8½@8¾c; flats, fine 9¾@10c; choice 9¼@9½c; fair 8½@9; small, fine 10¼@10½; choice 9¾@10c; fair 9@9½c; Ohio flats, fine 9½@9¾c; choice 9@9¼c; fair 8½@8¾c; Picnic, fine 9½@10c; Swiss Cheese, fine 11@12c; choice 10½@10¾c.

FOREIGN MARKET.

BOSTON, Aug. 12—Cable advices of this date from the principal markets of Great Britain to Geo. A. Cochrane, give butter markets as active and higher on the finest descriptions of table butter. Finest Danish is in light supply, which throws the demand largely on to Canadian, the fine quality of which gives it a strong hold on buyers. 21@22c is being made for the best description in boxes, and 20@21c in tubs. Irish butter is running very poor with prices most irregular. American creameries continue to be neglected, quality hardly good enough to meet the demand, and prices take a range all the way from 18½@20c. Imitations continue a very dull sale. Ladles show more improvement and fine June goods have sold at 15½@16c, but sales cannot be made at all freely over 15@15½c for the best of the current make.

Cheese markets are all again higher, and the demand very active, clearing arrivals promptly each week. Finest American and Canadian bringing 10½@11c, with some holders asking more money for fresh landed parcels.

MANCHESTER MARKET, ENGLAND.

Copenhagen wires:—The intense heat has ceased here, and colder, rainy weather has set in. Meantime the pastures look quite bare, and some of the farmers have to give their cows additional fodder in the house. Butter market, as I foretold you, is decidedly firm, and prices have an advancing tendency, but I don't think values will be raised this week yet. Arrivals seem short for the week, but cannot yet be ascertained. Orders large, all selling quickly. The official quotation has since been wired two kroner higher. Cooler weather with occasional rains prevail over the United Kingdom, and will help the make of butter and improve quality immensely, especially in transit. The Irish markets have been very firm during the week, with advanced prices for the higher qualities. Irish creameries and factories in good demand. Manchester market was rapidly cleared, last Tuesday, at three to four per cent over the previous week's prices for Danish. Consumption is large and growing, and though imports generally have increased, they are cleared at continually higher rates. Cork market reports an increase equivalent to 10,841 firkins to July compared with the same period of last year. Dairying throughout Ireland is receiving a great impetus, and the leading public markets are undoubtedly reviving as the most convenient center of exchange. The arrivals of Danish and Swedish advised for next week's North of England markets are 19,375 casks, 644 less than last week, and 1,916 Finnish, 44 less. Arrivals of Margarine via Hull 9,884 packages, and via Grimsby 6,256 packages. Dowdall Bros.

ANOTHER "ALPHA" TRIUMPH.

ROYAL AGRICULTURAL SOCIETY FIRST PRIZES.

The "Alpha" De Laval machines have just won another great victory over would-be competitive cream separators, in the practical working contest at the 1899 Annual Show, at Maidstone, Kent, of the Royal Agricultural Society of England.

This Society is probably the most important agricultural body in the world, and its Annual Shows are the largest and most important of agricultural exhibitions and contests held anywhere. The Society has conducted no cream separator contest since 1891, at which time the "Alpha" disc machines first demonstrated their great superiority over the "hollow-bowl" type of separator construction, so that the contest to be held this year has attracted a great deal of attention everywhere with those interested in dairying matters, and especially among separator manufacturers. Different manufacturers, from various countries, sent not only their own special engineers to superintend the running of their respective machines, but in some instances the inventors or chief constructors themselves.

The Royal Agricultural Show test of separators is by all odds the most thorough and complete attempt by any society or institution anywhere, the work differing in some respects from that of the Experiment Stations in that it is devised and conducted along the lines of practical operation, without regard to mere experimental possibilities. The test covered five days continuous running, every feature entering into the economical cost and practical efficiency of a separator being carefully analyzed, the Association's consulting engineer acting in conjunction with the official judges. The "points" taken into consideration were: Price, efficiency of separation, power taken per gallon, time taken per gallon, means of regulating thickness of cream, facility for dismantling and cleaning, mechanical construction, and freedom from froth, both from skim-milk and cream.

The contest was devided into two classes of machines—Hand and Power. There were six entries of Power and nine of Hand machines. The First Prize was 20£ or $100—in each class.

THE "ALPHA" DE LAVAL MACHINES EASILY WON FIRST PRIZE IN EACH CLASS, which while no more than anyone familiar with separators would naturally have expected, is nevertheless the highest endorsement any agricultural implement could possibly receive, and an endorsement of such character that its weight must be recognized in every part of the world.

The De Laval Separator Company,

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Agents make big money selling Universal Tinware Mender. Sells at sight. No soldering iron, acid, or resin needed. Cash commission or valuable articles given to agents. Send 10 cents for sample. S. S. AGENCY, Caton, O.

For Sale—Dairy and milk route in town of 10,000. Selling 45 gallons per day. Will lease 132 acre farm reasonable. JOE CRON, 726 W. 6th St. Bloomington Ind.

For Sale—Creamery and skim station doing good business, Has 160 patrons. Both plants equipped with best machinery. Full particulars on addressing WM. ROWSE, Norway, Iowa.

Farm For Sale—165 acres, 3 miles from county seat of one of the best counties in Western N. Y. Farm well located; good producing land in first-class farming section. Will be sold very cheap. If desired would take part pay in cattle. Would be pleased to correspond with real estate agents. BOX 386. Geneva, N. Y.

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada 32-52

Wanted—An expert Northern dairyman, graduate of Wisconsin Agricultural College, and of life-long experience, wants position in charge of southern dairy farm. Will work for salary or on shares, and furnish A No. 1 references. Address E. O. THORSGAARD, Streator, Ill. 26-3

Wanted—Man and wife to milk forty cows. Must be speedy and clean milkers. Man to care for cows in winter and in summer to work on farm between milkings. References as to character and ability required. State wages and references. LEWIS E. MURRELL, Lynchburg, Va. 26-2

For County Fair, Waukesha, the North-Western Line will sell excursion tickets at reduced rates from Ft. Atkinson, August 22 to 25, inclusive, limited to include August 26. Apply to Agents Chicago & North-western Railway.

For Fair and Fall Festival, Clinton Junction, Wis., the North-Western Line will sell excursion tickets at reduced rates from Fort Atkinson, August 21 to 22, inclusive, limited to include August 23. Apply to agents Chicago & North-Western Railway.

He Applied His Knowledge.

ED. HOARD'S DAIRYMAN:—For a number of years I have been a reader of your most excellent and valuable paper. As to whether I have profited or not by its teachings, the following figures best answer the question:

Twenty-eight head of full bred and grade Holstein cows and heifers on my Sunnyside Farm, managed by George P. Ashbocker, produced from Nov. 1st, 1898, to May 1st, 1899, 115,103 pounds of milk, for which I received $1,095.08 from the factory.

The milk fed to calves, that were raised during the period as above, is not credited the dairy in the above figures. Eight of the cows dropped calves in September and October, eight were farrow and twelve freshened during the six months from Nov. 1st, 1898. Five cows of this number gave 36,667 pounds of milk in six months. One of the number gave 8,947 pounds in the same time.

A full bred, two-year-old heifer, Aaggie Albans Queen Clothilde, gave 5,233 pounds milk in six months, while her mother, Aaggie Albans Queen, gave over 12,000 pounds milk in eleven months. The milk from the entire dairy was tested at the factory by a state milk inspector and tested 3.6%.

The dairy was not forced for a record, but was fed and cared for intelligently, without which no man can expect to succeed as a dairyman. They were fed the ration you formulated for me, which was published in the DAIRYMAN under d ate of Nov. 25, 1898, on page 830

My experience was that I got the best results at the milk pail by feeding the grain in three feeds per day instead of two. I think you will agree that there are not many non-paying boarders in this herd.

At the same time, I consider that there is still room for improvement, and with the help of a tried and true friend, the DAIRYMAN, I am going to prove to my brother dairymen that the above is not an extravagant statement. May you long live to spread the gospel of dairy truths to the farmers of this country, is the wish of

Jefferson Co., N. Y. A. E. HELMER.

Feeds and Productivity.

From fifty to seventy-five per cent of the total expense of maintaining the dairy herd is expended directly or indirectly for forage or food. If greater profits are to be secured they must be largely reached by cheapening the cost of the food. If we undertake to maintain in milk a cow of 1,000 pounds live weight, on clover hay alone, she would have to eat thirty-five pounds of clover hay per day. This would furnish of digestible material 2.38 pounds of protein and 13.86 pounds of carbohydrates (including fat multiplied by 2.25), which is very nearly a standard ration. If fed during the winter stabling period of 200 days, the cow will consume three and one-half tons of hay, which, at the ordinary price of clover hay in the Eastern states ($7 per ton), would amount to $24.50, which nearly equals the value of the products of many cows. Then, too, it would be difficult for the cow to eat thirty-five pounds of hay daily. In addition to the winter forage, the cow would require pasture for 165 days, which at twenty-five cents per week, would add nearly $6 more to the expense of the cow's food. It is evident that there can be no profit in keeping the ordinary cow at a yearly cost of $30.50. It may be said that the income from each cow should be more than the estimated cost of her food as given, but with a really good cow the difficulty is not removed, only slightly alleviated.

With present pastures and meadows it would require more than three acres of land to produce the hay, and two more to furnish the pasturage. If mixed hay or timothy is fed, the results would be still more unsatisfactory, since the ration would be too wide and the hay higher priced. Something might be gained by selling some of the hay and by purchasing some by-product rich in protein. It is evident that little profit can be secured if ordinary hay forms the larger part of the ration. If we turn to alfalfa, the millets, prickly comfrey, kafir corn or sorghum, they give no indication of furnishing a cheaper or more satisfactory forage supply than does clover hay. True, the clovers may be made to materially assist other species of plants to secure a food supply and to keep the land in good physical condition, but why add fertility to the land by means of clover raised and fed at a loss, when the moist soil already contains thousands of pounds of potential plant food which awaits a more intelligent husbandman? What useful purpose has the 36,000 pounds of the three leading elements of plant food in the first sixteen inches of each acre of average soil ever served? Most of it might as well never have been created, so far as the welfare of man has been concerned.

Sixteen analyses of beet soils made at Cornell University show 4,587 pounds of nitrogen, 4,267 pounds of phosphoric acid and 41,600 pounds of potash in the first eight inches of soil per acre. Allowing that an acre of soil eight inches deep weighs 1,200 tons, the total average potential plant food of the three elements was 50,453 pounds per acre, and probably more than half as much more in the second eight inches. Some rotten rock from a farm in Jefferson County gave 5.59 per cent of potash and .56 per cent of phosphoric acid, or sixty-seven tons (134,000 pounds) of potash and 13,440 pounds or more than 6½ tons of phosphoric acid in an acre of of rotten rock, eight inches deep. What an opportunity for hot plow shares and brains!

It would appear from many analyses of soil made in this and other States that most of the arable land contains vast quantities of potential plant food which can easily be made available for plants by a more rational system of tillage and cropping. But most of this plant food is lazy, and when a lazy or unskilled farmer owns this lazy food, there is so much loafing on the farm and in the soil that results are unsatisfactory. Is there a remedy for such conditious? I think there is at least a partial one. On a dairy farm the products of the cow form the staple, and the products of the corn field should form the staple food of dairy cattle. It is a little humiliating at this late date to urge upon farmers the necessity of raising corn and of building silos for preserving it. The ensilage question has passed the experimental stage; there is a cloud of witnesses to testify in its favor, and why a majority of dairymen still continue to feed hay almost exclusively as roughage passes comprehension. True, there are many imperfect silos still in existence; these were built before we had fully tested different kinds of construction, but for the last three or four years the best form and kind of silo has been definitely settled. As we know that best form of a dwelling house is a parallelogram from one-eighth to one-fourth longer than wide, so we know the best form of a silo is circular.

I can well understand why the dairyman does not make corn the leading forage crop if he has no silo. The acres of unhusked corn and stover, which remain into winter in the fields, in western New York, bear witness to the dreaded task of husking corn and storing feeble and bloodless corn stalks;corn stalks which, had they been harvested by machinery and properly stored, would have formed large quantities of succulent, acceptable, forage cheaply. The twelve to fifteen tons of green material, or four to five of dry matter, which may be secured from an acre of corn, may serve to reduce the cost of food maintenance one-half. But it is said that such large crops serve to deplete the soil of its fertility. Twelve tons of corn per acre would remove, in round numbers, sixty-seven pounds of nitrogen, twenty- six of phosphoric acid and eighty-nine of potash; in all 182 pounds of these elements of plant growth. Compare this with the amount of potential plant food found, as an average, in the sixteen soils analyzed, referred to above, and it is seen that there is enough plant food in the first eight inches of the soils tested to produce more than 300 crops of corn.

It may be said that plants cannot recover all this plant food. True, but no account has been taken of those vast stores of plant food which lie below the first eight inches of surface soil, much of which is available, or can be made so by intelligent tillage. Then, again, nothing has been said of the vast stores of plant food which the soil may receive from nitrogen-fixing plants and barn manures. "Never cross a bridge until you come to it," some one has said, but in this case it might be said, "Don't worry about the bridge of soil exhaustion, which will never have to be crossed if just a little intelligence is used in agriculture." Here, again, for the thousanth time let me reiterate the true principle of agriculture, so far as furnishing available plant food for the crops: Make available the lazy plant food already in the soil by tillage, drainage, cover crops, liming, or by any other means which will arouse the sluggish elements in the land.

Carefully preserve and judiciously apply the barn manures, and then if the most profitable results are not reached, purchase nitrogen, phosporic acid and potash in concentrated forms, and by careful tests find out what kinds and quantities of extra plant food are required in any given case.

Indian corn follows Indian corn most kindly. It is not even necessary to rotate it with other crops for a period of from six to ten years. Then, too, a cover crop can be maintained in the corn every fall and winter. Indian corn has few enemies, and is easily grown from inexpensive seed. If it were possible for one to originate an ideal forage plant—one which should possess the greatest possible desirable qualities and the fewest undesirable ones—he could not materially improve Indian corn, and yet comparatively little of it is raised and used in the dairy districts of New York. Hay still forms the staple roughage of the dairy.

Formerly there was a good reason for neglecting the cultivation of corn. In some localities the season is not long enough to ripen the larger and most desirable varieties. In all localities, the labor of cutting, husking, shocking and housing, when it could be housed without endangering its palatability, was so great, and the work so disagreeable to the farm lad, that it is no wonder the dairyman planted the minimum of corn and cut the maximum of hay,although the yield of the former might exceed by four-fold the yield of the latter. But now all is changed. No more cold fingers and cracked hands, no more tired, squatty corn stalks in the windy fields, no binding corn stover with weeds or a belated corn stalk.

If another view of the subject is taken, corn far outranks hay. It has been shown what vast quantities of lazy, unused plant food an average arable soil contains, and often the meadow makes this food lazier than it was when the meadow was first seeded. The soil becomes more and more compact as the meadow is retained; nitrifying organisms perish for want of air, warmth and moisture. Old plants are grown in the meadow, young plants always in the corn field. While some plant food is being liberated, on the other hand as much is being constantly locked up and made more and more unavailable in the meadow, where no tillage takes place. In the corn field, under good tillage, plant food is being constantly changed from the inert to the available stage. Long maintained meadows tend to produce undesirable physical conditions of the soil, while the cultivation of corn and other intertilled crops tends to improve the friability of the land and to make the soil more comfortable for the plants. Corn tillage tends to increase productivity, to unlock plant food and fit it and the soil for other exacting plants, as sugar beets and potatoes. Then the corn crop does not diminish productivity, but tends to increase it.

We should have discovered long ere this the wonderful value of Indian corn as a cattle food. As soon as a more general use of Indian corn in the dairy is recommended, we are met with the fact that to feed alone it forms too wide a ration. But this difficulty is easily met, for wherever maize is at its best, oats and peas thrive also, and these, in conjunction with a small amount of purchased by-products, (such as linseed or cottonseed meal), will serve to narrow the ration down to the accepted standard. Then, in addition to the large amount of acceptable roughage, there may be from fifty to seventy-five bushels of grain per acre.

The same general rules which apply to feeding cows hold in maintaining the productivity of the land. The cows should be maintained by home-raised food, and not by a bank account or on borrowed money. The assertion that cattle foods can be purchased cheaper than they can be raised is only applicable in rare cases, or when the farmer lacks skill in his business. The way to reduce the price of by-products is to diminish the purchase of them. While commercial fertilizers and by-products are valuable adjuncts to agriculture, they should never be purchased until the best possible use has been made of native fertility in the soil, barn manures and cover-crops, and every means exhausted to discover the best varieties of plants for a given purpose, and how to double the yield of them.

We have been studying the dairy question from the wrong end. We began at the rear or teat end of the cow; let the order be reversed and let us begin our studies at the front end, with what goes in at the mouth and the cost of it. Having started right, progression in our studies will be natural; and qualities inherited or acquired, milk mirrors, length of rail and teats, and their setting on, may be investigated with some hope that the mammary organs, being nourished and sustained by a full and rational ration, will adjust themselves in time to the supply of nourishment furnished, when we may view them as the result of intelligently applied energy at the front end of the animal. —I. P. ROBERTS, in *Country Gentleman.*

Milk Dilution Separators.

[Press Bulletin.]

Within the past few months there has been introduced to the farmers of Indiana, what is termed a dilution cream separator. This is not a separator as commonly understood by dairymen, where cream is separated from milk by centrifugal force, but is a specially constructed can,usually of large size, in which cream separates from milk by rising to the surface, by the common gravity process. The principal of creaming in this can, however, differs from that usually performed in the dairy through the mixing of water with the milk to assist the cream to rise. These specially made cans have certain peculiarities of construction and are advertised by the makers as "cream separators." The cans of different manufacturers differ in form and style, but the principal feature with all is to fill the can partly full of new warm milk and then at once add a large quantity of cold water. This of course dilutes the milk, perhaps one hundred per cent. In this diluted condition, the claim of the manufacturer is, that the cream will rise more completely and rapidly than if not diluted; that in twenty to thirty minutes it will all rest on the surface of the skimmed milk, which can be drawn off from below.

In 1893 the Indiana Experiment Station, for two weeks, carried on an experiment on the influence of dilution of milk on efficiency of creaming. The results of this work, as published in Bulletin 44 of the Station were, that a greater loss of fat occurs in skim milk when dilution is practiced, than with undiluted milk; that the loss is greater with cold than with warm water, and that by diluting the milk a poorer quality of skim milk for feeding is thereby produced. These results were in accordance with conclusions arrived at through similar experiments at the Vermont, Cornell, Illinois and Ontario College stations. The process of dilution was not to be recommended as a general practice.

These so-called separators are patented, and the Cornell Experiment Station,at Ithaca, N. Y., has recently published a bulletin describing and illustrating eight forms of them, as described in the Patent Office *Gazette.* Persons interested may perhaps secure a copy of this bulletin on application.

The farmers and dairymen of Indiana are advised not to purchase these cans. The price, as a rule, is exhorbitant and the practice of dilution is undesirable. But if the farmer wishes to secure the same results advertised by the makers of these cans, he may obtain them by diluting his milk in a comparatively inexpensive, round can, such as may be secured of any reputable dairy supply house,or can be made by any good tinsmith. Such a can, however, should have a faucet in the bottom, through which the skimmed milk may be drawn. In fact, if our farmers will set their milk undiluted in deep cans—say 18 to 20 inches deep and eight in diameter—set in cold water or cold room, they will get more satisfactory returns, than when set in shallow pans or crocks.—*Purdue Experiment Station.*

The Vicious Bull.

For a really vicious bull that is out with the cows in pasture any contrivance put on his head, when he has no horns, I do not believe, would be much of a success. It would be difficult to keep in place and he would be sure to break or pull it off. The owner should keep him in a box-stall opening into a small paddock with a bull-proof fence. Turn him loose in this, feed and water him from the outside and let him severely alone. This is generally the way such bulls are handled. The cows would have to be brought up to him and turned into a small enclosure where the bull or cow could be forced out again without the attendant going inside the fence. If I owned a herd of good cows and this was my bull, instead of a helmet on his forehead, I would put a good big bullet-hole there and send him to the shambles. I have two reasons for such a drastic remedy for a bad-tempered bull. In the first place that is the only treatment that will ever make him safe to handle. An experienced and nervy herdsman can often control and handle such bulls, but eternal vigilance is the price of his life, and depend on it, if you are afraid of the bull he will know it just as soon as you do. The second reason is based on the law of heredity that like begets like. The bull will just as surely transmit his disposition to his offspring as he will his color or any other of his individual characteristics. Further, a bull with a nervous and pugnacious disposition is nearly always noisy, restless and fretful, and practical and observing breeders know that such an animal is a bad breeder.

In my opinion a great many breeders fail

to see the importance of a kind and docile disposition, especially in a male animal, for if a bull is half the herd they have his temper in the same degree. The difference in the get of a bull with a vicious disposition and one that is kind, can be most readily noticed when they are being tied up for the first time or halter broken, and the bulls among them, when they get about two years old, will nearly always commence to show that they are a chip of the old block. There are bad tempered bulls in all breeds and the sooner they are sent to the butcher, it will, as a general rule, be the wisest way to cure them.—*Breeder's Gazette.*

The Pig and Its Possibilities.

During the first three weeks of the pig's life the milk of the sow is food and drink, therefore it must be the aim to furnish the sow with food that will produce the largest supply of milk. As sow's milk is naturally richer than the milk of any other animal, the aim should be to use food that will increase the milk flow, but not its richness, and this region is blessed with the cheapest material to produce this result. Recent extensive observations among thousands of farmers in Minnesota impress us that there is an indifference about availing themselves of the economic conditions at hand. We found, for instance, that oats ranged in price, during parts of May and June, from 25 to 35 cents a bushel and shorts from $10 to $14 per ton. A little use of the pencil will show that a ton of oats at the lowest figures given would cost $15.75, and one-fifth of them are in digestible hulls, and if ground the cost of it must be added. And yet shorts are more valuable, pound for pound, than oats.

In other cases rye, barley or corn was resorted to; an extremely rich food and very liable to cause fever, constipation, cough and thumps in pigs. The too frequent absence of pasture is lamentable. Grass cannot be omitted, if pig rearing and feeding are to be successful. Clover, of course, is king; but blue grass will be relished in the fore part of the season. Oats and barley, sown thickly will answer for a period, and it can be resown with rape. And fight as hard as they will, sooner or later, the farmer will accept the inevitable and adopt fencing, and will consider it a blessing. By the time their pigs are three weeks old, sows should be turned on pasture, after first receiving a liberal feed of thick slop of shorts, two parts, to one of corn or barley, and temporary shelter from sun and storm will be a great advantage, if they have not liberty to return to pens at will. But no more should be fed than sow and pigs will eat with a relish; and no pasture should be without water.

It will ever be found a great advantage to so prepare the food that pigs will learn to eat it with the sow, for then there will be no perceptible check of growth at the time of weaning. If sows are not to be bred for a second litter, it is best to let pigs nurse for three months, but liberal and judicious feeding should be practiced. If they are on clover pasture and receive shorts, as slop, soaked shelled corn can be fed as a part of their rations, on floors, with good advantage. If skim milk is abundant it is best to mix the shorts with it shortly before feeding. For young pigs of from four to six weeks of age, one pound to the gallon of milk will be sufficient and increase this with size to three pounds of shorts. It will be found that greater and more healthy growth will be the result, and many ailments will be avoided.—*Farm, Stock and Home.*

Cause of Soft Butter.

Some butter that is made in summer is often soft or mushy, though, of course, most of it is solid and of good grain. The reason why the soft butter is not of the same quality as the hard is that it is not made in the same manner—which, of course includes the handling of both the milk and cream. The softness of the butter is generally due to the temperature being too high, and this is why soft butter is the rule in most dairies during the hot months of July aud August. Perhaps the reasons why the difficulty is not overcome is lack of conveniences, pressure of other duties, and in some cases, ignorance. To over come all this keep things cool. Have the cream at the proper temperature, and if you cannot secure the means of making it so, it would be better to give up the idea of making butter during the summer, for it would be a great deal better not to make poor butter, even if you are interested in the smallest kind of a way, for it will ruin your reputation, and this once done it will be next to impossible to build up any kind of a business in either butter or cheese. Churn the cream—during the morning would no doubt be best—at a temperature of about 56 or 58 degrees, for this will prevent its becoming mushy. As soon as the butter comes in little granules about the size of grains of wheat, it is time to stop the churn. Should it look milky and not float well, pour in sufficient cold water to make it float. Having done this draw off the combined water and buttermilk, and pour in more cold water, almost filling the churn, and then revolve the churn rapidly about fifty times. I had this illustrated to me a few weeks ago at an institute, and the result was a lot of butter with each little grain standing out separately, extremely firm in texture and ready for salting.—*New York Witness.*

Misrepresenting the Case.

We must expect the opposition of a large majority of the daily press when the demand for increasing the tax upon colored oleomargarine is finally made upon the Federal Congress. General news editors, by reason of the multitude of subjects which they are compelled to treat editorally, write hundreds of comments upon passing events with only a very superficial knowledge of the subjects. Most of them tackle anything like "class legislation" with great gusto, and the news editor's effusions under this head are as likely as not to be the merest sophistry.

This is the way most of them are treating the oleomargarine question and they will doubtless continue to look at the matter with such perspicacity as might be expected from those who are half informed.

Most of the unfavorable editorial comments upon the proposed increase of federal tax on colored oleomargarine have been based upon the false statement that it was proposed to "put a prohibitory tax on oleomargarine." Then naturally the ground is taken that it is "class legislation"; "an effort to destroy a legitimate business for the benefit of competitors," etc., etc.

But these misrepresentations, while extremely annoying, are not likely to do any very serious harm to the cause of honest dealings. The fight will have to be made in congress and it will be easy to put the proposition before the people's representatives clearly; and with them outside influences are likely to be much more strongly in favor of than against the proposed legislation, which is not intended to prohibit the legitimate manufacture of a substitute for butter but simply to prevent its fraudulent sale as such. —*New York Produce.*

Hogs Want Water.

Hogs frequently suffer from lack of water, because farmers do not remember that whatever comes in liquid form is not a substitute for the clear and fresh water which all animals need. Put a little rennet in skim milk or heat it, and it soon turns into a curd which no one would think of taking as a drink. Yet both the rennet and enough of warmth to make it effective, are present in the stomach of a pig or hog. The rennet from pigs is by some preferred to that from calves. Always the first process in digestion of milk is to turn it into curd. Milk is regarded as constipating, especially after it has been heated, which brings it more nearly to curd condition, and thus absorbs the water in the stomach. A man needs a drink of water after he has eaten a bowl of bread and milk.

Most of the water that pigs get is as bad for drinking as skim milk. It is largely the water used for the washing of dishes or the freshening of salted pork. In this way the hogs get more salt into their stomachs than they require, and this also makes the hogs feverish and injures the quality of the pork. This sometimes makes the western pork, which is fattened in large droves and get little salt, better than the pork made by farmers who keep but two or three pigs and feed them from the swill barrel filled with a mixture of skim milk and salt water. If fed as it should be, with only enough corn at the close of the fattening and without an excess of salt, the eastern pork is much the best. The water in which salt pork and beef are freshened is highly nutritious, as a good deal of its strength goes out with the salt when it is freshened for cooking. But the great majority of hogs would be healthier if they had enough fresh water, fruits and vegetables to offset the excess of salt that most of their drink contains.—*Boston Cultivator.*

Hogs Killed by Soap Suds.

A recent bulletin from the Cornell Experiment Station, shows that wastes from hotels caused deaths in swine herds, and that the cause of death was the soap powder used in dish washing. This powder contained fifty per cent carbonate of soda. When fed to pigs in quantities ranging from one-half of one ounce o five ounces daily, sickness and death followed with some of the symptoms which are sometimes seen in hog cholera.

Transfers of Guernsey Cattle from July 15 to 31, 1899.

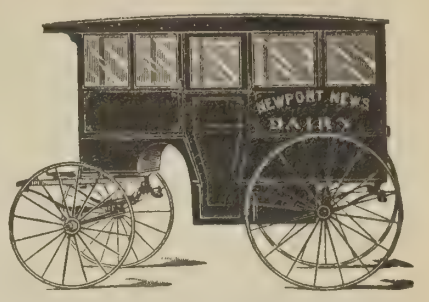
ILLUSTRATION.

PROSPERITY AND ERTEL BALING PRESSES.



That prosperity makes prosperity is being demonstrated again in the experience of thousands of farmers this year, with the Ertel Victor Hay and Straw Press, and the "Gem" Full Circle Hay and Straw Press. More farmers have been able to buy their own

presses than ever before, and each purchaser has enjoyed greater prosperity through possessing it. The "Gem" press is the most durable one ever mounted on wheels. It is built wholly of wrought steel, excepting a few gray iron castings, and its lightness and strength are strong points in its favor. Three men with two horses and a boy to drive can bale from ten to fifteen tons of hay a day, of which full weight will load into railroad cars. Because of the convenience of the methods of packing, "Gem" bales are preferred by purchasers of baled hay. The "Gem" is so easy of operaton that it can be operated by one horse.

Full particulars of the Ertel presses can be obtained by writing to the patentees and makers, George Ertel Co., Quincy, Ill.

The World Cannot Show Its Equal

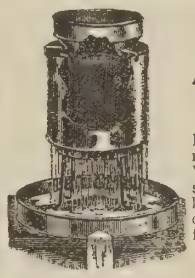
In STYLE, CONVENIENCE and DURABILITY.

Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairyman at bed rock prices. For description and price address,

THE NATIONAL WAGON CO.,
Chillicothe, Ohio.

Mortgage Lifters.

That's what dairymen call our light running hand separators, because they increase the yield of butter about 25 per cent. and improve the quality, which means higher prices. We **guarantee** each and every



Empire Cream Separator

to fulfill every claim we make for them, and give perfect satisfaction to every purchaser, or your money back.

Send for catalogue of the most complete line of hand separators in America. Agents wanted.

U. S. Butter Extractor Co., Newark, N. J.

The YOUNG AERATOR And Cooler

Needs no water or ice, removes all odors and gasses. Warranted to keep milk sweet from 6 to 12 hours longer than any machine on the market or money refunded. Circulars free.

W. H. YOUNG,
Box 135, Aurora, Ill.

THE Wisconsin Curd Test.

It shows the quality of every patron's milk and points unerringly to the milk that causes Bad Flavor and Gass Cheese. For full particulars address

A. J. DECKER, Fond du Lac, Wis.

GLUTEN FEED.

CHAPIN & CO., Milwaukee, Buffalo, Boston, St. Louis. Manufacturers' Agents for **GLUTEN FEED.** This is the best and cheapest milk-producing feed for the money. Contains 26% digestible protein. It keeps sound and sweet. Sold in car lots. Inquire of your grain dealer. Price based on its milk-producing value. For Wisconsin orders address **CHAPIN & CO., Milwaukee.**

DON'T BUY COTTON SEED MEAL

Unless guaranteed analysis is attached to each bag.

The American Cotton Oil Co.'s

Cotton Seed Meal carries a red tag showing Guaranteed analysis to be not less than

Ammonia	8.50%
Nitrogen	7.00%
Protein	43.00%
Crude Fat and Oil	9.00%

See that the name of the American Cotton Oil Co. appears on the red tag.

The "Ice-Milk" Question.

ED. HOARD'S DAIRYMAN:—My letter in HOARD'S DAIRYMAN of July 28th has caused some parties to write me on the subject, inquiring as to some details, etc. The first was from a prominent creamery proprietor of Wisconsin, who seems to be one of those who catch on quickly. He actually wrote me that he at once had tried to make "Ice-Milk" and what surprised me more—"succeeded!" He had pasteurized (temperature not given) milk, such as received at his creamery, then frozen it, sold some in that city and people claimed it "delicious and out of sight."

Now I believed all this, but when he wrote me he was going to ship me a sample, I doubted the result for many reasons. The sample arrived in a sealed jar, packed in a box with some ice around it, but as it had been shipped by express it very likely has been without sufficient ice on the way here.

I put it in ice-box here, kept it two days there, opened it and found it slightly acid. After leaving it till next day it was clabbered and of pleasant acid taste.

Now this experimenter need not be discouraged at all, because he could never expect success in that manner. While I do not know all he did, still I can give some causes for failure.

Average milk, as generally supplied to creameries, in hot weather especially, will never answer for perfect pasteurization; *the better* (or more free from germs and impurities) *the source, the more perfect will the pasteurized product be.*

This has been plainly shown by the bacteriological examinations of our milk which are made here regularly at the biochemical laboratory of the Agricultural Department, as whenever from some cause the number of germs to the cubic centimeter was larger in our natural "sanitary" milk, then also the number was larger in our pasteurized milk; for instance, when 50,000 germs in "sanitary" would leave 200 or 300 in the "pasteurized", then 2,000 or 3,000 in "sanitary" might leave only from twenty to forty germs, and repeatedly be entirely free.

This was also proven by Professor Russell's statement to me, on examination of our report for last year, that he was surprised that our results from pasteurized milk here, at the "Pasteur Milk Laboratory," were so far superior to theirs at the dairy school; which he could only explain as being caused from a better source of milk supply.

His results with milk from their private dairy farm at the school, were as good as ours. But I especially wish to call attention to the fact, that the milk selected from their milk patrons at the school and used for pasteurization had contained from 500,000 to several millions of germs.

Now here is my point, that such milk will not answer for ice-milk for city supply.

But if pasteurization has the proper effect on milk, and the acid germs are thoroughly killed, I have found that such milk by and by will clabber, but yet be perfectly sweet to the taste. Such has been my repeated experience, whenever pasteurized milk had been kept too long and unduly exposed.

Therefore we must first make sure of a comparatively pure milk and secondly of a very carefully conducted pasteurization and cooling. A drop of cold water getting into the pasteurized milk would cause failure. Another inquiry as to ice-milk came from a

NEW YORK FIRM, OPERATING TWELVE CREAMERIES

in that state. They also desire details as to freezing milk and cream for shipment, which just now I can not give. But as their main object seems to be to secure large quantities of cream for butter making purposes, they certainly would not require any freezing of such, but merely the pasteurization and rapid and thorough cooling (or shipping hot in summer.) Either way would guarantee a perfect condition of cream when received at their factories. The difficulty will be in the shipping expense.

INQUIRY AS TO EFFECT OF FREEZING OF CREAM OR MILK FOR BUTTER MAKING.

The same party asks for light on the above point, and thereby seems to me to show that they do not read HOARD'S DAIRYMAN carefully enough. Several years ago I started the discussion of said question, and my fixed opinion and knowledge that

FREEZING NEVER INJURES EITHER MILK OR CREAM FOR BUTTER MAKING PURPOSES,

provided it is properly treated, has since been confirmed over and over again in HOARD'S DAIRYMAN and especially so by Prof. Robertson, of Canada, who goes so far as to say, that *freezing actually improves the milk for butter making;* in which view I really think him to be correct, as he generally is. To make a perfect butter of such, simply depends on application of somewhat higher temperature and a perfect and sufficient starter for ripening and somewhat longer time. Try it next winter and you will soon be able to make as firm butter from frozen milk as you ever made. J. MOLDENHAWER.

Washington, D. C.

Another Butter Fake.

HOARD'S DAIRYMAN has received the following letter, by reference from the persons to whom it was addressed:

HENDERSON CREAMERY CO.,
Henderson, Ky.

GENTLEMEN:—After experimenting for some time, I succeeded in producing butter without the use of any chemical of any nature, and for the past two years have made and sold it, (on a very small scale) and those who have used it declare it to be first-class. Buying milk here at twenty cents per gallon, the butter costs me twelve cents per pound to make, and sells for twenty-five cents per pound.

In your section where milk costs so little there should be a market for my process of butter making. This butter has the keeping quality of any ever sold in this market. I would be pleased to hear from you before proceeding further. Yours truly,

— —

We suppress the name of the writer because we do not want to give him any advertising and place temptation before any weak brother who might think it a good scheme just "to try" the wonderful discovery (?).

One gallon of milk weighs, approximately, 8.6 pounds, and if it should test 10%—which is more than twice as much as ordinary milk tests—would contain 86-100 of a pound of fat, which is not more than enough to make one pound of butter. Hence where milk costs twenty cents per gallon, and does not test over 5% fat, the amount necessary to make one pound of merchantable butter would cost at least forty cents, instead of twelve cents. As there is no way by which a man can draw twenty gallons of liquid from a ten gallon cask, or make eight ounces equal to sixteen ounces, so there is no process whereby a man can make a pound of good, merchantable butter without he has .80 to .85 of a pound of pure butter fat.

There are processes by which butter and lard can be stuffed with water, and the resulting compound weigh more and look bigger, but in either case the product is adulterated, and only resembles genuine butter and lard,

"—— as mist resembles the rain."

Animal Matter a Necessity For Poultry.

It is well known that poultry, when allowed to range at will, eat considerable quantities of animal matter in the form of insects, worms, etc.

How necessary this animal matter is to the health of fowls, and especially ducks, was strikingly brought out by recent experiments at the New York State Experiment Station. Two lots, each of chickens and ducks, as nearly alike as possible, were used in these experiments. One lot in each case was fed a ration of mixed grains and skim milk, or curd, containing no animal matter, the other a ration of mixed grains, with animal meal and fresh bones or dried blood. The two rations were about equally well balanced, although the "animal-matter" ration contained a little less protein than the "vegetable-matter" ration. The distinctive difference between the two rations was that in the one case two-fifths to one-half of the protein came from animal sources, while in the other it all came from vegetable sources.

Two trials were made with chickens.

In each trial more food was eaten by the lot receiving animal protein, the gain in weight was more rapid, maturity was reached earlier, less food was required for each pound of gain, and the cost of gain was less.

During the first twelve weeks of the first trial (starting with chickens one-half week old) the chicks on animal meal gained fifty-six per cent more than those on the vegetable diet, although they ate only thirty-six per cent more; they required half a pound less of dry matter to gain one pound and each pound of gain cost only four and one-fourth cents, as compared with five and one-fifth cents for the grain-fed birds.

During the next eight weeks the cost of

Butter Bred Bull Calf, 10 MOS. OLD, a Little White.
Very handsome . . . Send For Pedigree. **$50.** J. P. BRADBURY Pomeroy, Ohio.

gain was seven and one-half and eleven and one-fifth cents, respectively. The animal-meal chicks reached two pounds in weight more than five weeks before the others; they reached three pounds more than eight weeks sooner, and three pullets of the lot began laying four weeks earlier than any among the grain-fed birds.

With the second lot of chicks, starting at six weeks of age, the differences were in the same direction, though not quite so striking; thus showing that the great advantage of the animal nitrogen is in promoting quick, healthy growth and early maturity, rather than increasing the tendency to fatten. * * *

The results were most convincing, almost startling, in the case of ducklings fed the contrasted ration.* * * Before the experiment had been long under way it was noticed that the animal-meal birds were developing rapidly and evenly, but the grain-fed ducklings were becoming thin and uneven in size. It was sometimes almost pitiful to see the long-necked, scrawny, grain-fed birds, with troughs full of good, apparently wholesome food before them, standing on the alert and scrambling in hot haste after the unlucky grasshopper or fly which ventured into their pen, while the contented-looking meat-fed ducks lay lazily in the sun and paid no attention to buzzing bee or crawling beetle. The thirty-two meat-fed birds lived and thrived, but the vegetable-food birds dropped off one by one, starved to death through lack of animal food, so that only twenty of the thirty-three were alive at the close of the fifteenth week of contrasted feeding. They were then fed for four weeks on the meat-meal ration and made nearly as rapid gains as the other lot at the same size two months before, but they never quite overcame the disadvantage of their bad start on grains alone. * * *

In conclusion, then, it may be said that rations in which from forty to fifty per cent of the protein was supplied by animal food, gave more economical results than rations drawing most of their protein from vegetable sources. The chief advantage was in the production of rapid growth, although the cost of production is also in its favor. While inferior palatability may have had something to do with the marked results, especially with the ducks, the whole bearing of these experiments and others not yet reported seems to indicate that the superiority of the one ration is due to the presence in it of animal food.—*Farmers' Bulletin No.* 10.

A Believer in the Escutcheon Theory.

ED. HOARD'S DAIRYMAN:—In answer to D. E. L's., Roper, South Carolina, question in your paper of August 4th, in regard to the escutcheon theory, would say that I can tell a rich milker by the escutcheon, tell how much milk they will give daily; also how long they will continue to give milk, and it applies to all breeds alike. All breeds have the same shaped escutcheon.

My advice would be to get a "Treatise on Milch Cows" by M. Francis Guenon, published by Orange Judd Co., 245 Broadway, New York, and study it as I have, and see whether the escutcheon is a fad or not.

I have a full blood Holstein cow with a first-class, Order 1st, Flandrine escutcheon, which I consider one of the best cows in the world. She gave one hundred and two pounds of milk at two milkings. This cow is only milked twice a day, and averaged ninety-five pounds a day for a week. She is also a persistent milker. I tested her when four years old, with the Babcock test on winter feed, and from seventy pounds of milk tested four per cent butter fat, which was one day's milk. She is now eight years old. When she made this record of one hundred two pounds this season, she was fed four pounds bran, two pounds gluten and two pounds corn meal, besides grass.

As you are aware, all the big record cows are milked three or four times a day, and given all the grain they can eat, so you can see what this cow might have done had she been treated the same.

I have from this cow, eleven daughters and grand daughters, besides a number of sisters.

I would invite all lovers of good stock to call on me at any time, and I think that I can convince them that the escutcheon theory is all right. J. JAQUAY.

Madison Co., N. Y.

State Control of Feeding Stuffs.

In several European countries the sale of concentrated feeding-stuffs is regulated by the government. A few eastern states are following this lead by inaugurating laws regulating the sale of certain feeding-stuffs, which laws are quite similar to those controlling the sale of commercial fertilizers. In Maine, for example, each package of concentrated feeding-stuffs offered for sale must bear a tag on which is stated the net pounds of feed contained and the address of the manufacture, together with the percentage of protein and fat guaranteed. A statement of the brand of feeds sold must be filed with the director of the state experiment station and a tax of ten cents per ton paid. Upon receipt of this sum the station issues the tags which are affixed to the packages. The feeding-stuffs coming under such control are linseed meal, cotton seed meal, pea meal, cocoanut meal, gluten meal, gluten feed, malt prouts, dried brewers grains, hominy feed, rice meal, oat feed, fish scrap, etc. Corn, buckwheat and other cereal grains are not included. The Massachusetts law differs somewhat from that in Maine, but requires analyses of feeding-stuffs to be published by the station, together with the names of the manufacturers.

The effects of these laws are very wholesome and they are welcomed by reputable dealers, who find it difficult to compete with those who practice fraud. Referring to the cotton seed meals analyzed before and after the passage of the law, Director Lindsay of the Massachusetts station writes:

"While fully one-third of all samples of cotton seed meal received at the station during 1897 proved to be seriously adulterated, thus far, in 1898, not a single adulterated article has been discovered."

A constant source of fraud is the illegitimate use of oat hulls. Oat hulls are worth about the same as wheat chaff for feeding purposes. They are turned out by the oat-meal factories in enormous quantities. Unscrupulous dealers buy these hulls by the car load, and mix them with corn meal, milling products, etc., and sell them to the unsuspecting for a mixture of ground corn and oats.

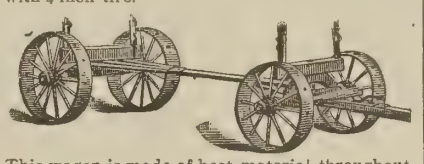
Every state east of the Mississippi now has a law regulating the sale of commercial fertilizers. These laws were made necessary by unscrupulous dealers who can easily deceive buyers. It is probable that laws controlling the sale of concentrated feeding stuffs will be adopted by one state after another until there is quite a general system of regulation. The expenses of such a system are small and insignificant compared with the advantages which naturally follow.—W. A. HENRY, in *Breeder's Gazette*.

Summer Milking Place.—Some Evils Which Threaten the Quality of Milk.

I would like to ask your dairy readers where they milk their cows this summer? I mean is it in the long regulation stable under the hay barn which has sheltered the cattle all winter, in the barnyard, or in an open shed outside?

If past example counts for anything, I think that in the majority of cases the milking will be done in the winter stable, and I would like to point out a few of the evils that threaten milk quality thereby.

Usually the winter stable and its surroundings undergo a semblance of cleaning every spring. That is, the accumulated manure of the frozen months is removed and spread on the fields. This is good as far as it goes, under the "never-too-late-to-mend" principle, but if it stops there it does not go far enough. While the mass of the compost has been carted away the odor remains behind, its retention favored by the absorbing nature of the ground, stable floor and walls, which perhaps have not been free from smell for years. The facility with which fresh-drawn milk absorbs foreign odors is well known, and to subject the lacteal fluid to such a severe and unequal test as to draw it from cows surrounded by impure air, and yet expect it to retain its natural flavor and quality, is foolhardy. The advice is often given to carry the pails of milk from the stable as soon as drawn from the cow, presumably to get it out of a polluted atmosphere, but is it not more rational to get at the cause, and remove the pollution?



Thorough airing, by throwing wide open both doors at the ends of the long stable, is all right as an auxiliary measure, and should never be neglected, but it does not get at the root of the evil. Dairymen, either do one or two things:—either do not milk cows in your winter stable this summer, or if you decide so to do, first thoroughly renovate and purify that stable. This can be done by scrubbing the stanchions and whitewashing the walls with two heavy coats of lime. Then use land plaster liberally in all the corners and on the floor, particularly where there are depressions and moist places. This is a great absorbent and deodorant, and will add to the value of the resulting compost.

Also pry up a few planks at intervals across the stable, and underneath, scatter plaster with a liberal hand. Then clean the stable regularly every day, not once a week or a month, as is too often done during the summer months. By the above plan you can keep the atmosphere of an old stable sweet and pure, insuring milk quality, while to continue in the foul rut is dangerous and almost criminal. I speak thus plainly because I know how pervalent the custom is of milking cows through the summer in these old winter stables, with at most only a superficial spring renovation. Of course those with more modern stables can the more easily deodorize them, but thorough daily ventilation is necessary to all.

The old-fashioned way of milking in the barnyard is good enough, providing the cows become accustomed to it. To make it successful it means that the animals must be so docile that they will not start off and walk over the legs of the milker before he is through, or gore one another promiscuously about the enclosure. The open milking shed furnished with stanchions is not in such universal use as its advantages would warrant. Its natural location away from the stable insures cleanliness of surroundings and purity of air, while the cows standing in stanchions have all the restraint secured by a stable. I much prefer it for summer milking, unless the winter stable has been renovated thoroughly as above.—*Boston Cultivator.*

A Low Wagon at a Low Price.

In order to introduce their Low Metal Wheels with Wide Tires, the Empire Manufacturing Company, Quincy, Ill., have placed upon the market a Farmer's Handy Wagon, that is only 25 inches high, fitted with 24 and 30 inch wheels with 4 inch tire.

This wagon is made of best material throughout, and really costs but a trifle more than a set of new wheels and fully guaranteed for one year. Catalogue giving a full description will be mailed upon application by the Empire Manufacturing Company, Quincy, Ill., who also will furnish metal wheels at low prices made any size and width of tire to fit any axle.

Mr. Wheaton's Canadian Dairy Notes.

Canadian Dairy Exports and Canadian Butter and Cheese.

ED. HOARD'S DAIRYMAN:—The one thing more than all others, perhaps, that is interesting in Canadian dairy circles just now, is the very much increased demand in Great Britain for our creamery butter. In some respects the demand is almost phenominal. It began early in the season and has continued without abatement till the present time, and even now there are no signs of its falling off. Exporters at Montreal report a regular stream of orders coming in and during the past few weeks a gradual advance in values has taken place.

One of the chief reasons for this very satisfactory condition of affairs is undoubtedly that the English consumer has suddenly evinced a decided preference for Canadian brands. Of course he has not become convinced of the good qualities of our butter in a moment.

The good quality of our creamery butter and the marked improvement that has taken place, during recent years, have been important factors in inducing him to seek butter for his bread on this side the Atlantic. Then in addition to all this, very effective work has been done by our dairy commissioners' department in recent years in letting the people of the old lands know that we have good butter and are able to send it forward by means of our complete chain of cold storage facilities, in good condition.

Another fact that has served to develop the market and create a demand for the article, is that our butter manufacturers and shippers have adopted the plan of shipping the butter regularly every week or two, in a fresh and palatable condition. Generally speaking, there is comparatively little butter stored on this side to what was the case a year or two ago. Many creameries now ship direct to some reliable British commission house regularly every fortnight, and get what the butter sells for, less commission, freight, etc.

The activity in the export butter trade is shown by the fact that no less than 20,000 packages left Montreal last week for the British markets. The total shipments from Montreal, from May 1st to August 2nd, this season were 126,174 packages, as compared with 71,184 packages for the same period in 1898, an increase of nearly 56,000 packages. Shipments from New York have been much more liberal of late, though not yet equal to last year. For the same period as above, the total shipments from New York were 30,216 packages as compared with 35,593 packages for the corresponding time in 1898, a decrease of about 5,400 packages, leaving the net increase in shipments from Canada and the United States, so far, 50,613 packages.

One would imagine that such a large increase in supplies, from this side, would have some effect in reducing values. But such is not the case this year. Cable orders received from the very beginning of the season, have shown a gradual advance in prices without a break, a condition of affairs never before experienced in the history of this trade in Canada. And still there is no abatement, and last week's cables called for more butter at one shilling to two shilling better limit.

With this condition of affairs existing in the export trade, things could not help but be brisk on the local markets here. Last week (August 5) Montreal figures for choice creamery were 19½ to 20 cents per pound. Some creameries in the eastern townships are reported sold at 20¼ cents per pound. There is also an active demand this year for dairy butter for export prices going as high as 15½ cents for select lots.

At these prices for creamery butter, dairymen have no great cause for complaint. They will certainly pay the man, who has good cows and looks after them well, a good profit, and may leave a balance on the right side for the poor dairyman, but we are doubtful of it. The make, so far as the exports show, has been much larger than last year. Many farmers, because of the increased demand and the scarcity of good feeding cattle and stockers, have this season patronized the creamery in preference to the cheese factory, as it enables them to raise more calves. Whether these calves, raised from dairy cows, will make good beef animals, remains to be seen.

The butter industry is not alone in the matter of advancing prices, and an active demand for goods. The cheese trade is also active, with values very much in favor of the producer. There is certainly a better consumptive demand in Great Britain for Canadian cheese, than was the case a year ago. This is reported to be due to greater industrial activity in the Old Land, and a consequently greater consumptive demand from the working man. Then it is also reported that the English make is a little short, and in addition to this, it must not be overlooked that we started this season with practically no old cheese on hand, so the way has been clear all along for shipping our cheese regularly, and getting them into consumption early.

There has not been a season for many years in the cheese trade in which there has been so little storing of cheese as has been the case this year. There is no great accumulation of stocks, either here or in England, and with our dry August weather upon us and a consequent falling off in the milk supply, there is not much fear of any great buying of stocks for future markets. Though our exports so far show an increase of 91,000 boxes over those of last year for the same period, there does not yet appear to be any more than what will supply the current demand. Prices are now at a point where it may be a little risky for speculators to load up with heavy stocks.

There are reports to the effect that several factories that have been making butter till now, have begun to make cheese, as they considered there is more money in it at present prices. We hardly think, however, that many will do this so long as the butter market continues as it is as present. Several districts in Ontario show a large falling off in the make lately, which may materially affect our exports later on.

Cheese last week (August 5th) touched the ten cent limit at Montreal, and the ruling prices at the local markets were nine and one-half to nine and three-fourths cents per pound, which is pretty high for the last half of July make. Factorymen were not very anxious to sell, especially at western factories, many of them holding for the even ten cents. It, however, is not wise to refuse a good thing, more particularly when the goods are nearly ready for shipping. This week will likely see most of the July make out of the factorymen's hands, when the local markets will be clear for August goods.

Reports, as regards the quality of this year's make, so far, show quite an improvement over last year. This is no doubt due, in a large measure, to the better conditions for making, and the fact that better prices furnish an inducement to patrons to take better care of the milk. It is also due, in no small degree, to the fact that many factories have this year greatly improved their curing facilities by putting sub-earth ducts and ice boxes in the curing rooms. By being able to control the temperature better, the makers have been able to make a little softer cheese that meets the wishes of the British consumer better than the stiff kind, which it is sometimes necessary to turn out in order to overcome the very hot and unsatisfactory conditions of many curing rooms.

Makers are now getting their dairy exhibits ready for the fall fairs. The dairy exhibit is always an interesting one at a Canadian fair, and exhibition authorities are always ready to do all they can to make this feature a success. No pains are spared in the way of refrigerators and accommodation for butter and cheese. Liberal prizes are offered and every inducement thrown out to get makers to exhibit.

There is one feature of it, however, in which we think an improvement can be made, and that is the entering of more new competitors into the contest. With a few exceptions, the same makers exhibit year after year and the prizes go largely to the same parties. This, of course, is all right so long as they deserve the prize, but we must confess to a desire to see more new exhibitors than there usually are, both in the cheese and butter classes.

The leading feature of the dairy department this year of the Toronto Industrial Exhibition, which takes place from August 28th

GOLD DUST
THE BEST
Washing Powder

Gluten Feed is used by nearly all successful dairymen, and has become a necessary article for any dairyman farmer who wishes to keep pace with the successful men in his line of business.

Gluten Feed increases the flow of milk, improves the quality, keeps the cattle in the best possible condition—in fact, helps you make more money out of your dairy. This is not cheap talk. We mean business. Gluten Feed is all and more than we claim for it, and, best of all, a trial proves it. Sample of Gluten Feed, Milk Talk Pamphlet, and circular illustrating the "Value of Butter Fat in Milk," all FREE if you address

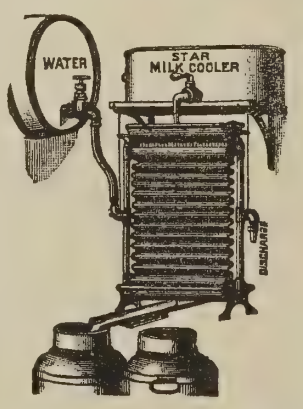
Is it CHANCE, is it GOOD LUCK, or is it MERIT that has enabled the patrons of



GENESEE SALT

for five years in succession to win the SWEEPSTAKES PREMIUM of the NATIONAL CREAMERY BUTTERMAKERS ASSOCIATION? Certainly they were good buttermakers, but perhaps the Salt had some little to do with the result. The winners were as follows:

In 1895.....F. G. OLTROGGE
In 1896.....THOS. MILTON
In 1897.....H. N. MILLER
In 1898.....S. HAUGDAHL
In 1899.....R. T. MCCOLL

Study your own interests, use GENESEE SALT, and write to our General Western Salesman, Mr. F. A. TRIPP. 34 Clark Street, Chicago. Or address

Yours truly,
THE GENESEE SALT COMPANY, New York.

Star Milk Aerator
AND COOLER.

If you have milk worth cooling at all, it is certainly worth while to cool it thoroughly. An efficient Milk Cooler will cool to within two degrees of temperature of water used; the Star does this and also AERATES.

If you would like to know the reason why, send for 1899 Catalogue of Sanitary Dairy Apparatus.

To be had for the asking.

STAR MILK COOLER CO., Haddonfield, N. J.

COAL TAR BUTTER COLOR

Is prohibited by law in Austria as detrimental to the public health. Over one-half the butter in America is colored with coal tar dye. Do you want to know how to sell it? Send to us for the material for making the test and we will mail it to you free of charge.

Thatcher's Orange Butter Color

Is a pure vegetable color, free from deleterious substance. It gives butter

THE DELIGHTFUL JUNE TINT

So well known among users of high grade butter. It is healthful. For sample bottle send to

THATCHER MANUFACTURING CO., - Potsdam, N. Y.

to September 9th, will likely be the international butter making competition. We are not aware that any applications are in from American makers, but the competition is open to them if they wish to enter it. For our part we would like to see several makers from your side take a hand in this competition, as it would be mutually helpful to all concerned. Considerable interest has been shown in this contest by Canadian makers and we are likely to see a large number enter for the prizes. The more the better, however, as the contest should be more of an educational feature, than a means of disposing of a few hundred dollars in prize money.

Toronto, Canada. J. W. WHEATON.

Paraffin as an Adulterant of Oleomargarine.

By GEORGE F. GEISLE. Reprinted from the Journal of the American Chemical Society.

One often hears of adulterated food, but rarely are such sophistications of a nature that they may be deemed injurious to health. The recent finding of paraffin as an adulterant in a number of samples of commercial oleomargarine may therefore prove of interest.

Though paraffin has been mentioned as an adulterant of chocolates and candies, the use of such an indigestible substance as an adulterant of oleomargarine seemed so improbable that the actual separation of the paraffin was required to convince some skeptical minds.

Its use in oleomargarine is by no means new, for I first observed it in a commercial sample in September, 1893, and reported the fact to the New York State Department of Agriculture. The general properties of the fat of the sample, its behavior during saponification, and the abnormally low specific gravity indicated an irregularity and the probable presence of paraffin. Although the sample under examination amounted to only a few grams, sufficient of the unsaponifiable matter was obtained from the same to show that it was paraffine It was impossible at the time to get more of this particular sample, or duplicates of several others in which paraffin was found, between that date and March, 1894, when I was enabled to prepare an exhibit of the paraffin extracted from one of the samples.

About this time experts of the Department of Agriculture, in the course of their inspections in New York and Brooklyn, found quite a number of samples of oleomargarine which, upon analysis, were found to contain paraffin. Some of these were analyzed by Drs. Love, Waller, Stillwell and myself, and the amounts of paraffin in the various samples were found to range from 9.72% to 11.25%.

The publicity given the matter at that time, possibly caused a discontinuance of the use of paraffin in excessive quantities. At least, I did not again observe any positive indications of paraffin in the customary analyses of any of the numerous samples examined, until about six months ago, and subsequently, when I found paraffin in five different samples which had been taken by the experts of the department in their regular inspection of grocery stores, restaurants, etc., in New New York and Brooklyn. One of the samples, a one-pound print, and which had been sold for butter at twenty-two cents per pound, enabled me to make three exhibits of the extracted paraffin. The amounts of paraffin found in these samples ranged from 5 to 11.76%; in other words, from three to a little over six pounds per sixty-pound tub. The strip of paraffin extracted from commercial oleomargarine, which I exhibit herewith, amounting to forty-three grains, is a little short of the amount actually coutained in one ounce of one of these samples.

The extent of the character of the adulteration, it is almost impossible to determine, since much of the goods are sold secretly, and in many instances palmed off for butter to unsuspecting purchasers and customers. That much of the "oleo," in this market, is sold under the guise of butter, is evidenced by the testimony of witnesses under oath in hundreds of cases prosecuted in the courts of this city, during the past few years. The samples, which the inspectors take, represent only a small percentage of what goes into consumption.

It is pertinent to say that the object of the use of paraffin in oleomargarine is not to cheapen the article, but to make a more homogeneous fat mixture, by preventing the separation of the fats and oils, and also to affect the general consistency and appearance of the mass, and its behavior under the trier in sampling. One of these samples was with difficulty distinguished from butter by physical tests.

The use of paraffin, under these conditions, naturally gives rise to the query, What affect has it upon the system? I have been unable to find any records of researches as to the physiological effects of paraffins, which throw much light on the subject. Paraffin is generally regarded as an indigestible substance. This is undoubtedly true of paraffin taken into the system by itself. An interesting physiological question, however, presents itself in connection with the use of this substance in oleomargarine for the following reasons:

1. The paraffin is dissolved in the vegetable and animal fats, constituting the oleaginous part of the compound.

2. The fat mixture in most cases melts at the normal temperature of the body.

3. The fat mixture is in a highly emulsified condition.

Although paraffin is an unsaponifiable substance, it is a question whether, under the above conditions, some of the paraffin is not absorbed in the system along with the other fats, and whether more serious disturbances may not arise, than could be expected from the ordinary digestive disturbances attributable to the indigestibility of the greater part of the adulterant.

Communicability of Tuberculosis.

"In an elaborate paper, read before the Albany, New York County Medical Society, Dr. Edward Moore characterizes, as very weak and inconclusive, all the evidence that has ever been presented to show that tuberculosis can be communicated in any possible way from man to cattle, or vice versa. If the germ was originally identical, he believes that it has been so modified in each case, that it can live only in cattle, as the case may be, and must die harmlessly when transferred from one to the other. Everybody must earnestly hope that this view will ultimately prevail. If it does, Dr. Moore will rank as the pioneer in correcting a wide-spread and most injurious error."

There should be an exhaustive investigation of this subject by scientific men, and the truth definitely established.—*Country Gentleman.*

Saltpeter in Cornstalks.

In "Bulletin 49" of the Kansas Experiment Station, issued May, 1895, is a report by Prof. Mayo of some interesting and important investigations concerning the poisoning of cattle from eating corn stalks unnaturally loaded with potassium nitrate, commonly known as saltpeter. Not having ever seen these observations given to the general public, through the agricultural press, it has occurred to the writer that possibly a summary of them might not be without interest to stockmen, as it may throw light on some possibly otherwise obscure cases of cattle poisoning, says Prof. W. A. Henry in the *Breeder's Gazette.*

In this bulletin it is detailed how a Kansas farmer grew corn on a piece of land previously used as a hog-lot. Some stalks of corn so grown were thrown in the manger of a bull confined in the stable. After the bull had picked over the stalks (without ill results) about four large armfuls of them were taken out of the manger and thrown into the barnyard, where they were readily eaten by a drove of cattle coming from the pasture. The next morning seven dead cattle were found in the yard, lying in positions which indicated little or no struggle before death. In another instance forty cattle out of a bunch of 120 died, after being fed on cornstalks cut and cured for fodder corn in August. In these cases, and a third one, which is reported, an examination of the dried cornstalks showed them to be loaded with saltpeter. On this Prof. Mayo writes:

"A casual examination of the samples of cornstalks received, revealed the presence of large quantities of nitrate of potash (saltpeter). Beneath the leaf sheath, which surrounds the stalk just above the joints, the nitrate had crystallized in fine white crystals which resembled a white mold, but was easily recognized by tasting with the tongue. Around and in the cut ends of the stalks were solid masses of almost pure potassium nitrate. If a stalk were cut in two and tapped lightly upon a table, the crystals of potassium nitrate would be jarred loose and fall as a fine powder upon the table. Upon splitting a cornstalk the crystals in the pith of the stalk could easily be seen with the unaided eye. The bitter cooling taste, so characteristic of potassium nitrate, could be obtained by placing a small bit of the stalk in the mouth. On lighting a bit of stalk with a match it would deflagrate, burning rapidly like the fuse of a firecracker. A chemical examination of a quantity of stalks gave 18.8 per cent of the dry weight of the stalk nitrate of potash."

In another instance, the saltpeter in the dry stalks amounted to 25 per cent of their weight. It is certainly very unusual for the corn plant to take up any such amount of this chemical as is here reported, but facts are stubborn things, and it is well for the stockman to be posted in this matter in order to avert what might prove to be a similar disaster. Corn which is grown on old hog-lots or in corrals or other places where much manure has accumulated is apparently most liable to reach this dangerous condition, but one case is reported by the professor where there seemed no apparent cause for such a heavy loading up with the chemical.

Tests made by Prof. Mayo of feeding potassium nitrate directly to cattle showed that doses of from half a pound to a little over a pound were capable of producing death with animals weighing from 500 to 1,200 pounds each. From the chemical examination of the cornstalks made, the professor considers it entirely possible for them to have contained enough of the chemical to have caused the death of the animals as reported.

It is certainly most anomalous for the cornstalk to load itself with this usually not too abundant fertilizing constituent of the soil. Such cases seem almost beyond belief, but for the present it is well to accept the statements as they stand and keep a close watch. The bulletin names no antidote for poisoning in cases like these. Potassium nitrate is so rapidly soluble and so quickly absorbed by the system that probably nothing can be done after the chemical is once in the animal's stomach.

Beware of Cheapness.

BEWARE of the butter color that an agent claims to be *"just as good"* as W. R. & Co.'s Improved, but which he offers at a cheaper price.

There is not and never has been a color *"just as good."*

Why should any one be obliged to offer a color at less price if it is *"just as good."*

While cheap colors may be cheap in price, they are expensive to use.

THE FARMER AND THE ADVERTISEMENT.

"I paid a shilling for my binder twine this year," said a northern Illinois farmer, "while my brother-in-law, a mile or so down the road, got his for nine cents. He read the advertisement in a farm paper he takes. I didn't read the paper. He laughed at me yesterday and said he saved enough on that one deal to pay for the paper for years. And I guess he did."

Oleo Make for Year 1898-9, 87,800,000 Pounds.

The government year, beginning July 1st, opened up with a boom in the oleomargarine trade in Chicago, the same as the year closing June 30th, went out as a record breaker.

For the year ended June 30th, 1899, the fourteen factories of the United States made a total of 87,800,000 pounds of oleomargarine, compared with 57,516,136 pounds the year previous, and 45,531,207 pounds the year ending June 30th, 1897.

The internal revenue office records show that the new year promises, if nothing occurs to check it, to eclipse the year just closed, as greatly as the output of the past year exceed the make of 1897-8. At such rate the butter businesss of the country will be demoralized as it never was demoralized before.

During July just passed, the Chicago oleomargarine factories turned out 50,158 fifty-pound tubs of oleomargarine, against 29,057 tubs in July of 1898, and 13,000 tubs the corresponding month of 1897.

Last month there were issued from the Chicago Internal Revenue Office, 847 retail licenses to sell oleomargarine. A year ago there were 479 licenses issued in July, and two years ago 123.

The make of oleomargarine for this country as far back as the government has records expressed in pounds, is as follows:

Year.	*Pounds.*
1888	21,513,537
1889	34,325,527
1890	35,664,026
1891	44,392,409
1892	48,364,155
1893	67,224,298
1894	69,632,246
1895	56,958,105
1896	50,853,234
1897	45,531,207
1898	57,516,136
1899	87,800,000

The local oleomargarine makers have dozens of agents out, inducing retailers, to take out licenses. One agent was heard to remark a few days ago, that there would be fully 2,000 licenses in this district this year, compared with a few over 1,700 last year.

The food commissioner has made no move yet to appoint his assistants and get to work. Governor Tanner is out of the state, a fact which is a boon to the oleomargarine makers, as this failure to get the food commission at work, gives them just the opportunity they desire to get all the retailers in line with $48 each invested in licenses, which will be an incentive all through the year, for them to violate the laws, and risk prosecutions which they would not otherwise risk.—*Chicago Produce.*

Harvesting Soy Beans and Cow Peas.

We are in receipt of many letters asking how to harvest and thresh soy beans and cow peas, and how to prepare to sell them in 1900 for seed. Three out of five who try to enter the seed trade will be disappointed. The cost of selling a few bushels will eat up the profits. Seed will be so abundant and cheap next year it will not pay. We advise that the crops be harvested at that stage that will make the best hay or fodder. If wanted for hay, cut soy beans when in full bloom; when cut at that stage there will be no hard, woody parts to waste. The plant is, at that time, in a state of maturity, having most of the qualities that we desire in what we call hay—the protein stage.

Cow peas may stand until the first pods get full grown but not ripe. This is especially necessary if they are to be fed to young stock of any kind. At this stage they have the bone, muscle, hair and wool elements in them, and not too much fat. We wish we could impress feeders that fatty foods are positively hurtful to growing stock. A little corn or fat making feed, is needed in cold weather to keep up animal heat. Hundreds of thousands of pigs, colts and young cattle are annually stunted and dwarfed by a food where the fat is out of all proportion to the bone and muscle making part of the feed.

The margin is so small now we must look into these details; the observance or neglect which may turn the scale to a failure instead of a success. To express it another way, growing animals must have a protein feed, and fattening animals, food rich in fats. To those who want to feed fattening stock, milk cows, brood sows and breeding ewes, let peas and beans get to that stage we call fodder. Let the seeds get into a hard dough. At this stage pea pods will begin to turn yellow and dead leaves at the base of the stem turn yellow. The beans must be thoroughly field cured and the seeds get hard and dry, for the reason that in a hnndred pounds of soy bean seed there is only a small fraction less than seventeen pounds of oil or fatty matter. If they are bulked damp, they will heat and mould. Peas are not so rich in fat and will stand bulking sooner.

Cut with mowing machine for hay. Peas are hard to pitch off the wagon. We take a hay knife and cut the load the long way, and cross cut it two or three times, when they are as easily handled as common hay.

This hint will save much backache and sweat. When you can't put them under cover, and must stack outdoors, cut swamp grass, crab grass or any green growth, put it on as soon as cut, and it will mould and turn water like a tin roof. Brother farmers, you have in these plants that which will build up your soil, fatten your manure pile, and with it fatten your soil; and increasing crops will come to you each year with fat stock to sell every month in the year; also the granaries and pocket book will be full, and best of all, the "jewel of contentment will be entrusted to your keeping."

But to him who will use them to still further impoverish his soil, we give a word of warning. The plants are rich feeders, and when fed on the farm will add immensely to the enrichment of the soil; when sold off they will as rapidly deplete it. Their deep tap roots bring to the plants and store in the seeds the phosphates and potash; and the roots fill the soil with costly nitrogen, taken from the air. Ninety-five per cent of all this will be left on your farm if you feed it at home, and carefully save the waste. Make up your mind how you will use this gift and act accordingly. Will you be a builder or a destroyer? We have a number of very promising experiments to report later. We wish the readers of the *Rural World* could see what a great crop is growing today, where ten years ago almost nothing could grow.--ROBT. C. MORRIS, in *Rural World.*

Poultry For Profit.

There are very few farmers who realize how much money they get from the poultry that are produced on the farm. If they study the matter up they will find that the hens in the barnyard pay more for the food they consume than almost anything else, in fact except the indispensable horse, whose value is hard to compute, being so much depended upon, so says a writer in the *Poultry Tribune.* The farmer can keep a hen for less than fifty cents a year. This has been proved time and time again. It is a poor sort of a hen that will not produce ten dozen eggs a year. The average price is about ten cents a dozen. Allowing the cost of keeping is fifty cents and that eggs average but ten cents a dozen the year through, it will be seen the income is 100 per cent on the investment of keep. If he keeps his poultry as he should, the average price will be nearer twenty cents a dozen than ten cents, for he will get eggs in the winter when prices are high. With all the increase in the products of the poultry yards of the country there has never been a year that we did not import eggs, and this importation has not fallen off, except as the tariff affected it, and the tariff of five cents did not cut off importation entirely. The United States is fast becoming a nation of poultry and egg eaters, because the wholesomeness of poultry and relative cheapness of eggs, as compared with meats, is becoming better understood all the time, and the result is that the demand for poultry and eggs grows nearly as fast as the supply is increased, and the average rises slowly year by year. No one need hesitate about going into the business of raising poultry from any fear that there will be an oversupply. A low price always meets an increased demand, and this fosters an appetite for eggs and poultry, which is satisfied when eggs go up again, and the business keeps on growing. It will keep on indefinitely, for poultry can and will be kept with good profit when the country is much more thickly populated than it is at present.

MILKING TUBES AS PREMIUMS.

Pilling's Silver Milking Tube, One New Subscriber or $ 0.40 | **Moore Bros', Safety Milking Instrument,** Three Subscribers or $ 1.00

CONCERNING OUR ADVERTISERS.

On another page of this issue, appears the advertisement of the Foos Mfg. Co., of Springfield, Ohio. These people have long been patrons of our columns, and our readers will remember them as the manufacturers of the famous Scientific Grinding Mills and the Scientific Corn Harvester. Consult the advertisement,—it may contain just what you are seeking.

THE Genesee Salt Co. have arranged for a cheese contest among the users of this well known salt and the manner of conducting same will be of value to all who enter, as well as profitable to the winners. Their proposition is as follows:

The Genesee Salt Company will hold a Cheese Contest for regular users of the Genesee Factory Filled Salt for cheese in October, 1899, at Chicago, Ill.

Competent Judges will be selected and the result of their judgment sent to each contestant.

$150.00 will be distributed as follows:

SWEEPSTAKES.

The cheese scoring highest, irrespective of class, will receive $30.00 and will not be eligible for any other prize.

Only one cheese from the same factory may be entered in any one class.

Class 1—American Cheddars and Flats, 1st, $20.00; 2nd, $10.00.

Class 2—Twins and Young Americas, 1st, $20.00; 2nd, $10.00.

Class 3—Edam, Pineapple and all special shapes, 1st. $15.00; 2nd, $5.00.

Class 4—Brick and Block (Domestic), 1st, $10.00; 2nd, $5.00.

Class 5—Swiss (Domestic), 1st, $10.00; 2nd, $5.00.

Class 6—Best Box of Limburger, Brie, Club or other fancy cheese, $10.00.

All cheese will be sold at the market price and proceeds remitted to the maker.

An Entry Blank will be mailed to each maker applying to F. A. Tripp, 34 Clark St., Chicago, Ill.

A competent instructor will accompany the judges, and after the cheese is scored will write each maker his faults, if any; and suggest improvements.

With this contest the Creamery Package Mfg. Co., of Chicago, Ill., have joined, making additional prizes to those using Hansen's Rennet Extract and Cheese Color, scoring to be at same time and place. They offer the following prizes:

Class 1—American Cheddars and Flats, 1st, $20.00: 2nd, $7.50.

Class 2—Twins, Young Americas and Daisies, 1st, $20.00; 2nd, $7.50.

Class 3—Brick and Block (Domestic), $10.00.

Class 4—Best Box Swiss (Domestic), $7.50.

Class 5—Best Box of Limburger, Brie, Club or other fancy cheese, $7.50.

Those who wish to enter this contest, should send immediately to both of these firms for entry blanks, giving particulars of their respective offerings and securing such other information as might be wanted.

Grain Ration On Pasture.

ED. HOARD'S DAIRYMAN:—In your issue of July 28th, '99, page 469, Grain Ration on Pasture, you wish an answer from the party that wrote that article for *Practical Farmer*. Will say in answer to J. F. C., that you have answered the question as well, if not better, than I could myself. But if I used corn meal would prefer to use it when I first turn to pasture in spring, when grass is more or less washy. Later on would prefer the bran and gluten feed or the gluten feed alone. Our habit is to feed as much of such grain as the cow will consume and return a profit for the same by weighing milk and noticing the record sheet and feed accordingly. Hoping this will prove satisfactorily to J. F. C.

Columbus, Ohio. F. G. JOHNSTON.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

FAILURE TO GET WITH CALF.

We are having a lot of trouble in getting our cows with calf this year. The first one was an old Durham taken to the bull on November, and took her two or three times and then as she was no good we sold her. The second one was a good one, and slipped her last calf owing to some flax seed oil which was given her for the bloat, and we are now dosing her with Dr. Horne's powders. Do you think because she slipped her calf has anything to do with it? The third cow calved Jan. 23d, and did not come in heat until some time ago, and comes in heat regularly about every twenty-seven or twenty-eight days, and was served tonight on the twenty-seventh day. Is nymphomania contagious and could the two and three cows have caught it from the first.

San Luis Rey, Cal. J. H. Y.

ANSWER.

Your trouble is well nigh universal; constant bulling is ruinous always, and makes bad much worse. Don't understand just what you mean by asking, if the slipping of the calf had anything to do with it. It is all there is to it. Abortions and nymphomania are both infectious, and contagious, and if you read my printed direction, you will see I call the two twin sisters, etc.

GARGET IN HERD.

I am milking a herd of cows, that are afflicted with something like garget. Some of them when fresh will have a spoiled quarter. It will give bloody matter for a few weeks and then dry up. Some of them will give milk for a number of months and then, without any apparent cause, one quarter will swell and begin to give bloody matter, and it *usually* dries up and *never* gives as much milk afterward.

Albany, Ore. A SUBSCRIBER.

ANSWER.

In all such and similar cases, when a whole or a part of a herd is troubled as stated, there is one general cause, quite often hard milking, quite often poor careless milking, leaving the udder only partially milked. The best I can do for you is to find the cause and remove it. All the drugs in the materia medica will not be as good as a *thorough* physicking, mind I say thorough. Rub all the hard portions of the udder, only, with strong camphorated spirits, six parts, and common turpentine, two parts only. Rub tolerably hard, twice the first day, morning and evening, then only once a day for two or three days. When free from physic, give each full grown and sized cow, sixty grains of iodide of potassa in a little water, cold, as a small drench.

ANTISEPTICS FOR ABORTION.

An article in July 21st number of HOARD'S DAIRYMAN, "How an Attack of Epizootic Abortion was Dealt With," signed at end of article, Journal of the British Dairy Farmer's Association. This article speaks of antiseptic discs used for injections. Please write me the name of these discs and where to get them. C. B. D.

Ayer, Mass.

ANSWER.

I read the article alluded to and thought but little of it as a remedy for abortion. The antiseptics are all good, as far as they go, but don't go far enough. My best and proven antiseptic, and by far the safest, is Tilden's Bromo Chloralum, one to eight of water, cold. It is a positive deodorizer, disinfectant and antiseptic. Have used it for thirty years. Don't remember the English formula. We in this country can beat the old country as medicos in veterinary remedies.

INDIGESTION.

I have a cow that about one month ago, was swollen for two weeks. She would take spells grunting. She put corruption looking stuff through her. I sawed off her horns, thinking she might have the hollow horn. I noticed one of her horn's was running stuff, looked like the white of an egg.

Cordova, Ala. B. D. AKINS.

ANSWER.

Neglected hoven is the disease; at least, the direct cause. The first cause was, no doubt, indigestion, caused by some ill timed food. If in fair condition, immediately give full dose of physic, as per head of this column. After the physic, give her two drams of blue flag in two ounces of old whiskey, and four of cold water. Give one dose each day up to three doses only; rest three days, and then, instead, give her six drams of golden seal in the same quantity of whiskey and water. Give one dose of this each day, up to three doses. Wait two days, then repeat two doses; wait four days, then give one dose.

RETENTION OF PLACENTA.

About two weeks ago had a valuable cow take milk fever. She got well from it, but since that time she is unable to stand on her feet. She eats and drinks and chews her cud, but has no ambition to get on her feet. She gives but little milk; obliged to milk her lying down. She has not cleaned well and the odor from her is terrible. I have had a veterinary, but he is at a loss to know what to do for her. Can any of your patrons tell me what to do for her? The cow is a full blood Holstein cow. She never goes dry. Last year when she calved she gave thirty quarts of milk per day for a long time and just before she calved this year she gave about eight quarts per day. G. W. B.

Duluth, Minn.

ANSWER.

Your cow is in a bad condition. Rub hard all the legs three times a day with strong camphorated spirits, eight ounces; oil of cedar, four ounces; sul. ether, four ounces, and fish oil, cod liver is the best, twenty-four ounces. This is to be kept tightly corked and from the sun, and to be well shaken before applying. The cow must be raised and put in some form of a sling; first day, half an hour, morning and evening; next day, three-fourths of an hour, and so increase a quarter of an hour daily until she can do without it. Above all things don't let her get wet in any form. Let her have abundant, dry, soft bedding. If the bowels are not free, give her a moderate dose of physic each day for a few days, or until the stools are loose. Your veterinary is behind the ordinary, if he did not know just what to do. First, he should have removed all the placenta, by all means. This must be done at once. The milk is poisonous, and not fit for any use. Rub hard and long daily all the legs and well up to the body.

SUDDEN DEATH OF CALF.

We had a Guernsey bull calf, eleven days old, which died yesterday after four hours of severe pains in the stomach. Was weaned on the fifth day and put on skim milk and wheat middlings, as we always do, and it was apparently in perfect healthy condition. Bowel passage was dark green in the final.

Madison, N. J. SUBSCRIBER.

ANSWER.

The food no doubt was the cause, consequent upon fermentation in the stomach and bowels. Like all animals, a calf is subject to fatal attacks from many different causes, just as we ourselves are, and you may feed as you state for a long time and not have a recurrence. I don't like wheat middlings as food for calves, only in small quantities. So-called middlings are now-a-days a conglomerate mixture, not as we used to have them.

ILLUSTRATION.

We wish to say a word commendatory of our advertising patrons, the Crawfordsville Carriage and Harness Co., of Crawfordsville, Ind. Our readers will have noticed by the tone of their advertisements that they sell all goods direct from the factory to the consumer at wholesale prices. This means just what it says, too, as a single case in point will show. Take, for instance, the No. 116 "Hoosier Pride" end spring top buggy. This is a vehicle with which these people have taken special pains, with the result that it is a most remarkable case of

value for the money. It is constructed of good, honest material throughout, is well and handsomely painted and is trimmed in the latest and most tasty style.

The purchaser has the choice of several varieties of coloring in paint and in color and material for trimming. It is equipped with all the perquisites, such as boot, storm apron, etc., and sold under a positive guarantee of quality. The price, therefore, seems extremely reasonable at $40.50.

More remarkable still is the fact that they supply exactly the same buggy with the more expensive Brewster spring at the same price. If you contemplate the purchase of a buggy, carriage, light wagon or harness, it will certainly pay you to correspond with these people before buying. Ask them for their complete catalogue L. Kindly say that you saw this notice in our paper.

Horse Owners! Use
GOMBAULT'S
Caustic Balsam
A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from **Horses** and **Cattle. SUPERSEDES ALL CAUTERY OR FIRING.** *Impossible to produce scar or blemish.*

Canada Field Peas.

Peas are one of the foremost and most valuable crops that can be grown on the farm, and I must say the most neglected by the farmer. Perhaps no other grain crop except corn can be appropriated to so great a variety of profitable uses.

The grain is a healthful food, and rich in protein, and has a high feeding value. The straw contains valuable nutrimental material when properly cured, and is more relished by live stock than the straw of wheat, barley, rye or oats.

Peas can be successfully grown north of Latitude 42°. Ohio, Indiana, Illinois and southward the temperatures are too warm to insure a full crop of grain, but generally produces abundance of straw, which can be put to a profitable use for pasture and soiling. As a fertilizing crop, peas are excelled only by clover.

As a pasture for dairy cows, sheep and swine it is invaluable, especially when grown in conjunction with oats or barley, forming a combination of food and advantages, a summer pasture, rich in nutritious food, ready soon as the spring grasses begin to wither and fail. The pasture may be eaten down three or four times successfully during the summer, with a proper interval between the seasons of pasturing. In growing peas for fodder, a large yield of grain and straw can be obtained by a mixture of other grains sown in conjunction, resulting in greater advantages than when grown singly; the fodder can be fed directly to the live stock, avoiding the labor and expense of threshing and grinding the grain. In harvesting the crop great care should be exercised in the curing process.

Pea fodder is very easily injured by rain falling upon it while it is curing, it becomes bleached and loses much of its nourishment and palatable taste. Pea straw, properly cured, will be relished readily, but when allowed to get dead ripe, stock will eat sparingly of it, unless forced to do so by starvation. Hence it should be harvested just before reaching maturity.

The agriculturist in the Province of Ontario places great reliance in peas for a most important crop. From 15,000,000 to 20,000,000 bushels are raised annually; the greater portion of the crop is fed to live stock. Much of the success which Canadian farmers have obtained in preparing cattle and hogs for the market has arisen from the liberal use of peas in the food rations.

Peas are perhaps unexcelled for fattening cattle during the first half of the finishing period, but toward the close corn could be fed with greater advantage. Peas fed along with wheat bran or ground with oats or barley, equal parts by weight, furnish a healthful food for milch cows. Peas are beneficial for building up dairy cows for milk production, sustaining them in fine condition. Peas are superior when fed to swine as a sole grain food during the fattening process. Peas ground with oats or mixed with wheat bran or shorts, make an excellent food for brood sows during the nursing period; also a superior food for young swine, promoting growth very rapidly. Peas mixed with oats of equal parts, form a good food for ewes in milk, for the same reasons that have been given for their use to cows and brood sows. They are especially valuable for developing lambs for early market. Peas supply an excellent food for poultry, and will greatly increase the egg production.

Public attention has been rudely awakened to the necessity of doing something to prevent the rapid exhaustion of the soil. That so valuable a soiling crop as peas should not have received more attention is indeed surprising. Like all leguminous crops, peas have the faculty of extracting nitrogen from the air and depositing it in the soil for the benefit of other crops which follow. There are many practical points connected with this matter which must be of great interest to the farmer.

As a rule, farming operations are carried on for profit and not for pleasure. The rich man who farms for pleasure can easily afford expenses in the way of fertilizers which the practical farmer must necessarily avoid.

Winter wheat or rye should follow immediately after peas. By occupying the land with a growing crop, the losses of fertility are reduced to a minimum. Peas should be extensively grown for the value of the grain and for soiling purposes.

Vast areas of land in our favored country are well adapted to the growing of peas; as a consequence this source would add millions of dollars to the farmers' profit.

The value of this crop is too little known by the average farmer. Each year develops more intelligent interest and inquiry in its production. The difficulty in procuring pea seed, and the means to render easy the harvesting of the crop, have been the greatest obstacles in pea culture.

Pea harvesters have now superseded the scythe, and the seed problem can be easily overcome; one bushel of good seed procured and sown with care will produce about ten bushels of seed. With this amount of seed the farmer can commence operations at once. Soils containing 12 to 15 per cent of clay are best adapted to the growing of peas, but successful crops can be raised on a variety of soils. Since the pea is a hardy and vigorous grower, the land can be plowed in the autumn to great advantage and the peas sown early in the spring soon as the land is in suitable condition to be harrowed.

In sowing peas, a grain drill is preferable; peas should be buried to a depth from two inches on stiff clay to four inches on lighter soils.

When peas are sown broadcast and covered with the harrow only, and rain following, much of the seed will be exposed, hence use the grain drill.

The quantity of the seed to be sown depends largely on the character of the soil, and size of the pea. Rich and moist soils do not require as much seed as where the opposite condition prevails. The quantities to sow per acre will vary from two to three and a half bushels. The amount of seed should increase with size of the pea.

The term Canada field peas, as spoken of by the average farmer, signifies a lack of knowledge of the many varieties raised. The most suitable varieties of peas to sow will depend somewhat on the soil and climate, also for what purpose they are intended. White Wonder, Prussian Blue, Canadian Beauty and Lace White Marrowfat are great yielders. The best way to determine which kinds are the best suited to the varied conditions would be to sow a small plat of each of the several varieties. The Fall White Marrowfat is a good pea for soiling or for grain, and succeeds well under most all conditions.

Peas as a green manure are valuable; the most impoverished soil can be quickly renovated by plowing under a pea crop, preceded by winter rye. The rye should be sown in the autumn and plowed under in the spring when the heads begin to appear; peas should follow immediately, and in turn be plowed under. Ground thus treated would be fertilized in one season, and the mechanical texture would be improved.—*Practical Farmer.*

"Farm-for-Sale-Journal" Swindle.

A Michigan exchange says that preparations are on foot to introduce into that state a scheme that has been very profitable to those who have been engaged in it in Canada for some three years past, but very disastrous to the farmers there. It consists of the publication of a so-called "Farm for Sale Journal," which is to be devoted to descriptions of farms for sale, as its title indicates. The state is to be canvassed by agents, who first use arguments to induce the farmer to offer his farm for sale, and next, by glowing representations about the pictures and descriptions that are to be used in the journal, and of the vast circulation it is to have among farm buyers, they lead the farmer to sign a very shrewdly worded contract to pay to the order of these parties a sum of from $100 to $500, depending on the price put on the farm. Ostensilby the payment is to be made only when the farm is sold, but the supposed contract eventually turns up in the form of a promissory note for the amount, and it is said to be so worded that it can be filed in the recorder's office of the county where the land lies, in such a way as to make it a lien on the farm. The promoters of the scheme are not interested in making a sale at all, and don't care whether one is made or not. The payment that is to be made to them does not depend upon a sale being made, although the farmer is induced to believe that it does. It is a very cunning scheme, designed to get something for nothing, and it is said that a state like Michigan, well worked, will net the promoters of it at least $200,000. When one of these agents comes around will be a good time to whistle for the dog.—*Farmer's Review.*

THE JONES UMBRELLA "ROOF."

A NEW UNION TWILLED SILK "ROOF" $1.00

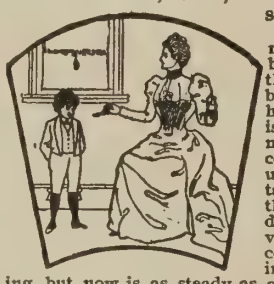
RE-COVER YOUR OWN UMBRELLA.

The Adjustable "Roof" fits any frame, requires no sewing, and can be put on in a minute. You can re-cover your own umbrella without the slightest trouble or moments delay.

Take the measure (to the fraction of an inch) of your old umbrella; count the number of outside ribs; state if the center rod is steel or wood; send to us with $1.00 and we will mail postpaid, a Union Twilled Silk 25 or 26 inch Adjustable "Roof" (27 or 28 inch, $1.25; 29 or 30 inch, $1.50). Umbrella "Roofs" all sizes and prices from 50 cents to $8.00 each, according to quality. If you are not absolutely satisfied in every particular, send the "roof" back, and we will refund the money *at once*, including stamps you have used for postage. Over a quarter of a million "Roofs" sold.

Booklet, "Umbrella Economy" with simple instructions necessary with your order.

All first-class dealers sell Jones Umbrella "Roofs."



The Jones-Mullen Co., 396-398 Broadway, New York.

Manufacturers of the highest grades of Umbrellas to the largest stores in the world.

OTIS H. KEAN N.Y.

For more than four years Mrs. Bender has been using Dr. Pierce's Golden Medical Discovery as a family medicine.

Mrs. E. A. Bender lives in Keene, Coshocton Co., Ohio, and from there she writes:

"As a cough remedy and blood purifier there is nothing better, and after having the grip is just the right medicine for a complete bracing up. Our boy has taken three bottles for St. Vitus's dance. He was very nervous and constantly jerking and twitching, but now is as steady as any one; in fact seems entirely cured."

The "Golden Medical Discovery" is a medicine that will help you no matter what ails you. This is true because it works directly at the roots of all disease—the digestive system, the blood, the nerves. Keep these in healthy condition and you cannot be sick.

Many of the cures of the "Golden Medical Discovery" seem almost miraculous. Its effect is almost immediate. It takes hold at once. It tones up the stomach, invigorates the liver, regulates the bowels.

It gets right into the blood and carries strength and comfort to every fiber of the body. It nourishes and invigorates the weakened, irritated nerves and puts the entire system in perfect tune.

It is a safe medicine. Safe for adults—safe for children. It contains no sugar, syrup, whisky, alcohol or dangerous opiates. Therefore, it does not create a craving for stimulants. It is distinctly a temperance medicine.

If a medicine dealer tries to substitute some other preparation when you ask for "Golden Medical Discovery"—look out for him. He is either ignorant or dishonest and you can't trust him.

If You Know

the value of a good separator, it is then only a question of which one you should buy.

The Kneeland Omega Cream Separator

costs less than any other, is simple, durable, perfect in results, guaranteed right, or money back. What more do you want? It's a money maker for every farmer. **Agents wanted.** Everybody, send for our free book on "Good Butter, and How to Make It." Address,

THE NEW BOOK
Feeds and Feeding

By Prof. W. A. HENRY, Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

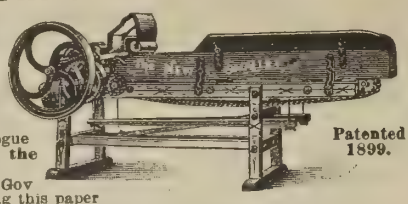
Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.



Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

The NEW Smalley

The Most Up-to-date Silo Cutter on Earth.

SMALLEY CUTTERS For 1899

are more complete than ever before. They will be furnished, if desired, with Patent Automatic Self-Feed, **increasing capacity greatly and diminishing labor of feeding nearly ONE HALF. Four sizes, Nos. 16, 18, 20 and 26.**

SMALLEY MFG. COMPANY, Sole Makers, MANITOWOC, WIS.

MAKE ONLY **SWEET ENSILAGE**

Ever since the ensilage system has been introduced in this country it has been the ambition and effort of siloists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste,

The best way to Shred Ensilage is with the

St. Albans Ensilage and Fodder Shredder.

It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail free a pamphlet on the subject.

ST. ALBANS FOUNDRY CO., ST. ALBANS, VT.

TORNADO Ensilage Cutter

IMPROVED FOR 1899.

Do you expect to put up Ensilage this Fall? If so, the **TORNADO** will do it better and faster than any other. Treatise on Cheap and Practical Silo Building mailed FREE. Mention HOARD'S DAIRYMAN.

Be Fair with Your Fields ***and they will be fair with you..... Listen a moment.***

Every time you take a crop off a field you relieve it of just so much fertility. You should do something to restore that fertility. Barn yard manure is the best fertility restorative known if properly handled and properly applied. Even a small amount can be made to go a long way and accomplish great good if finely and evenly spread. This cannot be successfully done by hand—it is work for a perfected machine. The only machine known which accomplishes this is

The KEMP MANURE SPREADER.

It will Double and Treble the Value of the Manure Heap.

It spreads all kinds of **fine and coarse manure evenly;** it makes no "skips;" does not dump a great load in one spot, but covers the entire ground evenly. Tears up coarse and lumpy manure and makes it fine. Better than anybody can do it by hand. **Spreads lime, wood ashes, salt, etc.,** equally well. With the drill attachment **it puts the manure direct into the open drill.** Made in three convenient sizes. Ask the opinion of anybody that uses one. **Write for illustrated catalogue.**

Kemp & Burpee Mfg. Co., Box 46, Syracuse, N. Y.

"PURIFINE" A BOON TO THE GREAT DAIRY INTERESTS,
A POWERFUL **Disinfectant** That is ODORLESS, NON-POISONOUS. Used in Creameries, Cheese Factories, Dairies and Stables.
IT DOES NOT Create an Oder to Destroy One.
SAN FRANCISCO, Sept. 22d, 1896.
I have used "Purifine" in cleansing milk cans and bottles and find it will remove the bad odor left by old sour milk more effectually than anything I ever tried.
E. A. GREEN. Sec'y,
Millbrae Dairy Company, Mission & 9th.
Applied with large quantity of water, which makes it cheap and convenient of use. It is invaluable to the cleanly dairyman or factory operator. Once try, you'll never be without.
SEND $1.00 FOR SAMPLE GALLON by Freight.
This powerful disinfectant creates no odor of its own, but will keep creamery, cheese factory and dairy pure and sweet. TRY IT ONCE.
FITCH CHEMICAL COMPANY, Bay City, Michigan.

Salt Surety
Is a good thing to have and costs little to get. It costs fifteen cents extra on every ton of butter to have a salt you can absolutely rely on. That is the first cost of using
DIAMOND CRYSTAL SALT
but, the fifteen cents comes back in fifteen different ways before you are through with it. It comes back in a saving of time, in added flavor to the butter, and weight. More—but why enumerate when the book, "The Salt that's all Salt," tells the story complete. It is yours for the asking.
DIAMOND CRYSTAL SALT CO., St. Clair, Michig ..

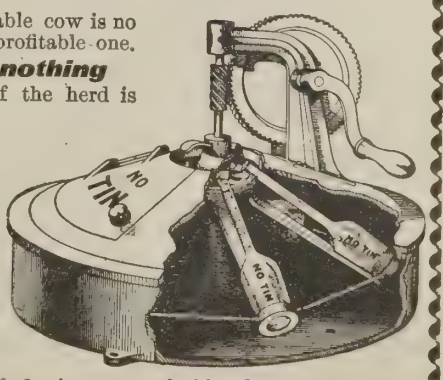
P. S.—We are the only Plow Factory in the United States selling implements direct to the consumer.

Separator Superiority.

There are thousands of people in this world who, when they buy an article of any ki d, are satisfied with nothing but the best. This is as true of the creamerymen as it is true of other people This "buying the best" has come to be recognized as a wise business policy because it involves a great measure of economy. So long as a creameryman does not know that he has absolutely the best machinery and appliances, just so long will he be dissatisfied in a measure, and in doubt as to how much his profits might be increased if he had the best. No such lingering doubt enters the mind of the man who buys a **Sharples Tubular Separator,** for if he has taken the pains to investigate, or even to make casual inquiry, he must know that he has the best separator that can be made or that money can buy. Of course there will be those who will try to dissuade and deceive him; they will tell him that something else is "just as good," and indeed these deceivers may go so far as to claim that something else is even better. Do not be deceived, however. The



Sharples Tubular Separator

will do everything that any other separator can do as regards effectiveness, and infinitely more. There is nothing with which to compare the Tubular. It stands alone in **Superiority, of Construction, Absolute Safety, Largest Capacity, Clean Skimming, High quality of Cream and Butter, General all around Efficiency, and economy of Operation and Repair.** If you do not already know these things to be facts, investigate at once.

Send for Catalogue No. 46 and learn all about the Tubular.

Grade up Your Herd..
The expense of feeding a profitable cow is no more than the cost of feeding an unprofitable one.
It costs comparatively nothing
to find out whether each member of the herd is profitable. The
NO-TIN... Babcock Tester
will give exact information. Is substantially built of cast iron, and made to use the ordinary Babcock bottles.

TEST EVERY COW and if she is not profitable, do not keep her. It is the best low priced tester in the world. Send for Catalogue, No. 71.
Elgin Manufacturing Co., Elgin, Ills.

AT THIS season of the year the preservation of milk demands that it be cooled in some manner.

With the

Champion Milk Cooler

May be Cooled and Aerated in one Process,

The Aeration removes all unpleasant oders from the milk. The cooling reduces the temperature quickly so that the keeping quality of the milk will be much improved.

The **Champion Cooler** can be used with ice, cold well water or running water. There is no other Cooler so convenient and so effectual.

No Dairyman can afford to be without one of these Coolers. The price brings them within the reach of all. Write for booklet, "Milk and its Care," which tells all about them.

Subscriptions in United States, Canada and Mexico $1.00 per year; 6 months 50 cents; 3 months 25 cents.

FOREIGN SUBSCRIPTIONS may be sent through Sampson Low, Marston & Co., St. Dunstan's House, Fetter Lane, London, Eng., or their agents including the leading news dealers and book sellers in nearly all foreign countries.

All countries in the Postal Union $2.04 a year; not in the Postal Union $2.56.

Correspondents must not expect us to acknowledge the receipt of letters containing remittances for subscriptions. The receipt of the DAIRYMAN is sufficient notification that the money has been received. The label on the paper will show date to which subscription is paid. In case of renewals if date on label is not changed within two weeks after remittance is sent, inform us at once.

Remit by draft on Chicago or New York, or Post Office or Express Order; never by personal check.

ADVERTISING RATES.

Twenty-five cents per line, (agate measure) 14 lines per inch, each insertion.

Reading notices, 50 cents per line (nonpariel measure) each insertion

JUDGE HOLT, of Minneapolis, has fined C. N. Brundage, agent for the Hammond Packing Co., twenty-five dollars for selling oleomargarine of a yellow color like butter. That is fair. When harlots put on the vestal garments of the bride, they should be punished for their fraud and deceit.

THE cut we give, this week, should call the attention of our northern breeders to the possibilities of dairy work in the south. If there are many such herds in the south, the northern breeders must look to their laurels and markets, or the acclimated cattle of Texas will capture the more southern trade.

THE long list of large premiums on dairy products to be won at the Wisconsin State Fair, Sept. 11 to 15, ought to insure a rare dairy exhibit from this great dairy state, not to mention the efforts which will be made by other states to capture premiums. The present State Fair management seems bent on giving all features of Wisconsin agriculture their proper place at the State Fair. It ought to be appreciated by large exhibits and attendance.

PASTEURIZING and preserving are words somewhat alike in sound but very different in practice. A Madison, Wis., milk dealer thought they were alike both in sound and practice and in consequence paid $25.00 and costs, to be instructed in the difference between the words, by the Judge of the Court.

The agent of a milk dope house in Chicago told the milk man that the dope would pasteurize milk. The milkman believed him then, but now he knows better. Knowledge is expensive sometimes.

THE MOST PROFITABLE CREAMERY BUTTER MAKER.

Every business has a certain percentage of cheap, unprofitable men. Invariably you will find them men who are afraid of giving good measure. Their motto is, "Do as little as you can and get as much as you can." The creamery business has its share of such men, but they are constantly being weeded out. The standard is being rapidly raised and as they have never taken pains to educate their minds to a broader and better understanding of their position and duty, they must go.

But there is one phase of the butter maker's position that should be understood and practiced more than it is. That is, his influence as an educator among his patrons.

A gentleman, who is secretary of one of the largest co-operative creameries in Iowa, in writing us a year ago on this question, said:

"A good butter maker does more than make butter. His influence is felt on the farm. A good patron does more than bring milk to the creamery. His influence is felt in the creamery. The patron is often stupid and stubborn and will not learn, and many butter makers don't care whether he learns or not."

That secretary hit the mark square in the center. The butter maker who will command the largest respect and the best pay, is the man who is capable of helping the patrons the most. He must be a well read and well posted man in the art of caring for cows, to be capable of giving good advice to those who need it.

He must be skillful outside as well as inside of the creamery.

Hence, we see why there is a constant growing demand for butter makers better educated in all that the business demands. Some men will educate themselves. They are good school masters for themselves even if they never attended a dairy school. Such men are appreciated by the people they work for. They know the value of the best thought and experience in this business, and they strive to get the patrons to accept of it.

Such relationships are especially valuable as more and more of the creameries become co-operative. In speaking of the butter maker of a large co-operative creamery in Wisconsin, one of its largest patrons once remarked to us:

"He is the best man we ever had among us. He helps us to select books and papers; helps to buy improved live stock and keeps *pushing us up* all the time. I think it is fair to say that in the eight years he has been with us, our cows have increased 25% in their butter product and it is nearly all due to his efforts. Of course we pay him good wages and no creamery can hire him away from us."

There is a whole sermon in that plain man's statement, which many creamery butter makers will do well to ponder on.

FROM A HERD OF JERSEYS SHIPPED TO SALTILLO, MEXICO,

By Mrs. W. G. HUGHES, Hastings, Texas.

Thoroughbred Stock.

ED. HOARD'S DAIRYMAN:—There are two stages in the process of convincing the farmer that he ought to pay the closest attention to the characteristics as well as the breed of his breeding stock. He will quite easily agree, as a rule, that poor, runty animals, whether bull or cow, will hardly produce valuable offspring, but when it comes to going down into his pocket for means of starting the better class of stock and weeding out the inferior, he hesitates and too often says that he hasn't the money just now.

What is to be done in such cases? Probably the everlasting sermon is the thing in its way, but the lively example is much better. An Erie county dairyman, without appearing to notice it, gave me a text the other day that is good for a host of sermons in this line. It was a very remarkable instance and may possibly be an extreme one, but it is fact and if other instances of the sort are less pronounced, they are all the more frequent.

There was a bull in the herd that was thought to be excellent for the breeding of cows. He was a thoroughbred Jersey and his reputation and market price were high. The owner was not satisfied with mere reputation, though, and he took careful note of his heifers. It was not long before he noticed a bad defect in them. The udder was imperfect. It was deep and heavy at the rear, but there was no forward end worth mentioning. Perhaps it should be said that the teats were placed too far forward, as this would explain the difficulty; but at any rate they were not only so far forward that they gave the udder fairly the appearance of malformation, but they were in pairs, making it sometimes hard to milk the heifers.

The dairyman kept the bull long enough to satisfy himself that the difficulty came from that source and then he sold him. I do not think that the reason for disposing of him was mentioned, but the price asked was quite enough to tell the story. There was no cheat about the sale.

Then the dairyman increased his knowledge of the wonderful results of prepotency as a corrective of faults in cows. Having a young imported Jersey, he bred him to some of the cows that had developed such one-sided udders. It is perhaps too early yet to make sure of results, but there is every indication that the effect of the changing of the bull will be complete and the herd will soon be rid of all further defect in the udder.

It has been rather slow in coming, but it must sooner or later be acknowledged that the individual animal is a variety all by itself in every case and that the best results in breeding must come from a study of the parents similar in its way to the study of plants for hybridization. Individuality in plants is comparatively slight, but it can be made considerable of, while in animals it is always large. We must not only know what an animal is, but what it can do, from a study of its progeny.

This work must, for the most part, be done for a long time yet, by the few. Farmers are still trying to cover the whole domain of husbandry. If they were natural students, the many ways, that they have to turn, would make it necessary for them to skim the surface of most things they undertake to do. There was a time when a little of this and a little of that, all pretty poorly done, brought a fair profit when put together, but that time is past. A farmer who is not a good deal of a specialist, at least in some direction, is lost, and the sooner he comes to realize the fact the better. It is not out of the question for him to profit by the successes of others, and in these days of voluminous literature of the farm every farmer can at least become posted, which is quite close to being specially educated.

JOHN CHAMBERLIN.

Erie Co, N. Y.

Let us Spray.

Cows and Flies.

ED. HOARD'S DAIRYMAN:—Mr. Lighty, of Pennsylvania, on page 508 of your paper, says "I find by spraying my cows and stable every morning and evening with coal oil I can materially reduce the flies. I use a little hand vaporizer that costs fifty cents."

I want to again tell you readers how useful I find the little tin spray pump I have used since the horn fly came. I use pure kerosene to spray the cows with every time we milk. I spray them wherever the flies congregate, except on the udder.

I find most flies on fore legs and shoulders of the cows. A pint of kerosene will spray thirty cows three times. In years past, long before the middle of August, we have darkened the stable in order to milk without danger of being kicked by the infuriated cows. This year the doors and windows are wide open and the cows stand quietly after being sprayed. They do not huddle together in the pasture as they used to and the flies are not nearly as numerous on the home farm, but in my pasture four miles away, and on farms around me, they are plenty. I began to spray early and killed off a large part of the first generation that hatched out.

I kept up the spraying and have held them in check. I do not believe the horn fly travels very far from one farm to another, and I do believe that if every owner of cattle would spray them thoroughly in spring and kill off the few horn flies that hatch out from last year's eggs, or wintered over flies, we would soon be rid of this costly pest. Let us spray. Amen.

C. V. PORTER.

Viroqua, Wis.

Separators and Cream.

ED. HOARD'S DAIRYMAN:—I have experienced the same occasional variation in the quantity of cream mentioned by F. L. Combs, Annapolis, Md.

It is conceded that to produce thick cream the cream aperture is to be made less, and that a higher rate of speed than the standard tends to the same result, in a degree; and that the opposite of the above gives thinner cream.

The inflow of whole milk it would seem must always be constant, and that the thickness of cream depends upon the ratio of the two outflowing streams. Shall we assume that this ratio can only be changed by changing the cream aperture? If the skim milk tubes could become contracted, clogged while the cream apperature remained the same, the ratio would be changed in the same direction as when the cream aperture is enlarged, and this should give us thinner cream.

Again, if the cream aperture becomes clogged, and the skim milk tubes are not, we get cream thicker than we expect. Is it impossible that either one of these outflows should ever get clogged? They certainly may be; but I have never observed close enough to demonstrate the fact of it in any given instance.

I cannot undertake to show the effect, if any, of extra high or low speed on the above but think it must influence the results.

I think it would be an easy task for a machinist to conduct experiments proving or disproving the above theory as to the ratio of outflow; but just the cause in every day work, is a different matter.

GEORGE A. GREENE.

Chautauqua Co, N. Y.

The Effect of Phosphates on Pasture.

In a recent interview in the Ottawa (Canada) *Free Press*, Prof. Robertson, who has just returned from England, related the following experiment by Dr. Somerville of the Durbon (Eng.) College of Science:

"Dr. Somerville has been carrying on investigations into the improvements of pastures. By a light application of Thomas slag (containing phosphates) a three acre plot has been improved to carry twice as many sheep, and yield nearly twice as much mutton per acre as the adjoining plot of three acres untreated. That was not due to an increased yield of produce on the field, but to an improvement in the quality of the herbage. When a part of each of the plots was cut as hay, there was little difference in the yield per acre. The application of phosphates had produced a plentiful growth of white clover on a treated plot; whereas clovers were hardly visible on the other one. There had not been any sowing of clover or grass seeds on the field. It was an old, permanent pasture.

Seasonable Notes From Michigan.

Feeding on Pasture.—Securing the Corn Crop.—Shooking Corn.—Shredded Fodder.

ED. HOARD'S DAIRYMAN:—Pastures are perhaps better than usual at this time of the year, although in some places close cropping has resulted in burned roots and the surface is as bare and brown as it is possible for a pasture to be.

There are still many farmers who do not feed anything extra during summer, and of course such are now complaining that the cows are drying up. This is the old cry, repeated year after year, yet it seems impossible to make them see their mistake in not providing plenty of succulent food for the dry time which is sure to come during July and August.

The time of year has now come when the corn crop is to be taken care of, and farmers ought to realize the importance of securing it in the best possible condition.

Corn is by all odds the most valuable crop we have, yet none is more carelessly treated. The stalks are fully as valuable as the ears, containing as they do so great an amount of nutrients, which, when properly treated, are relished greatly by all farm stock.

The trouble is with most farmers, they let the corn stand too long before cutting.

They do not realize how much the kernels will mature and harden in the shock, so sacrifice the fodder for the sake of allowing the ears to get fully ripe before cutting.

The size of the shocks is an important factor in determining the quality of the fodder. Put up in large size shocks the stalks do not become weather beaten, but will cure out nicely, while retaining the fine, pale green color which we so like to see when winter comes.

Another thing to be looked after is to see that the shocks stand firmly and do not get blown over when the first windy day comes.

We have made it a rule for several years, in fact, ever since we began to take special interest in the dairy, to cut our corn just as soon as possible. This is usually the last of August. We try to get it all in the shock before the first frost. There will be some soft ears anyway, and a few extra makes not half the difference that the damage to the fodder amounts to, in allowing the stalks to remain uncut waiting for belated ears to mature.

There is always plenty of work to do digging potatoes, putting in wheat, cutting and securing clover seed, etc., during the autumn months, so that the corn usually is left till the last thing. This results in considerable damage to the fodder, unless unusually well put in shock.

Many farmers hire the corn husked by hand outright at so much a bushel. Where this is done, it costs no more to get it done early. Exposure to autumn storms destroys much of the nutritive properties of the fodder, especially after husking.

As regards husking by machinery, I like it. Of course, there are some drawbacks, but it disposes of a long and disagreeable job in a few days' time. There are no cold fingers or strained wrists.

The fodder is nicely shredded and in good condition for use. The expense is about the same as for hand husking.

Some fear that the shredded fodder will spoil. Such fear is groundless. It will undoubtedly heat, but no harm results from it. It may be put in stacks outdoors anywhere. I have left it right in the field until needed, then drawn it in, a stack at a time, and found it had kept perfectly. There will be some corn scattered by shelling, but it is an easy matter to allow the hogs to gather this, which they will do in a very short time.

I think, however, that fodder shredded by a husking machine is hardly equal to that put through a modern feed cutter. It is not so finely cut.

In drawing to the machine for husking, broad runners attached to a stone boat, make a better vehicle than a wagon. It wants something low, very low down, so that the shocks can be turned or tipped upon them without lifting. Most farms are provided with something of the kind, a sort of sled, which does not draw so hard as a stone boat, and which is very convenient to use about the fields in hauling cultivators, plows, etc., as well as green feed for the cows during summer. We find one of these very handy about the place. Two teams will be required to keep the husker going, besides one to haul the grain to the crib.

Where the corn is husked by hand, great care should be exercised in binding the stalks afterward. The tops must be well secured or water will reach the center of the bundle.

Binder twine is better for this purpose than the stalks themselves, since they are so apt to be dry and brittle. Sometimes marsh hay is employed, and I well remember seeing my father twist his bands from the bundle which he carried to the field. It pays to buy twine to tie with, it is so much more satisfactory.

I hope every farmer who reads this paper will try, this year, to take better care than ever of his corn stalks. The majority have not silos, but with intelligent treatment much more could be realized from the stalks than is at the present time.

As treated upon many farms, half their value is lost entirely, and some of them are absolutely worthless as food for stock.

Now, a few words about those movable mangers. They are simply made to fit the width of the stall, and set in the proper position, far enough toward the manure trench so that the smaller cows are made to stand at its edge, the same as the larger ones. The space between this manger and the feeding alley is bridged over by a slanting platform of matched boards, so that the food slides into it easily.

The upright pieces, between which the animal thrusts her head to eat (and to one of which is fastened, vertically, the iron rod which holds the end of her neck chain) are placed just the same as in longer stalls, only nearer the manure trench, thus making a shorter stall.

We have tried having shorter platforms for the younger cows, before they attain to full size, but like those with movable mangers, best, since at any time they can be converted into full length stalls with very little trouble.

The front of our manger is higher at the sides than in the middle. Here there is a depth of but eight inches, while at each side they are sixteen inches. This is to prevent the cows from tossing the food from the manger as they are so liable to do while eating.

W. C. ROCKWOOD.

Michigan.

"We Want Sweet, Thick Buttermilk."

ED. HOARD'S DAIRYMAN:—I shall at once try to comply with your request to give some advice on the above question put to you by a dairyman of Montgomery, Ala. This gentleman states that his customers are delighted with his butter, but do not like his buttermilk, and asks where the fault may be.

Now it is of no use to find fault with one's customers, and we all have, in general, to furnish a product which suits their taste, no matter if it differs from ours or that of other civilized people, then all that remains for us to do, is to find out how to please them.

First, then I would ask your inquirer to keep in mind that "sweet" when applied to buttermilk in the south, and generally in the United States even, does not mean actually sweet, but only that which has a pleasant acid taste and is not very sour. But I have found in my eight years' experience in the creamery business in the South, viz; Kentucky and Tennessee that some people prefer a quite thick buttermilk, some a rather thin and fluid one.

Now, if your correspondent has his cream just properly ripened and not oversour, he will produce a rather fluid buttermilk, even if no water is added to the churning when the butter begins to "come." I always had plenty of customers for our "natural" (if I so may call it) buttermilk, produced from the churning of cream containing about 20% butterfat, and carefully ripened; but such buttermilk was always very fluid.

Of course I could make it get thicker, simply by leaving it at a somewhat higher temperature, say 60° F. until next day, and then stirring it vigorously; but we are very apt to get the buttermilk too sour by so doing.

The way in which I produce the heavy, thick buttermilk, not very sour, is by letting the separator skim milk clabber at proper ripening temperature, about 60° F., and then churning the same for about five minutes. But our main secret of success for selling any buttermilk in as fine condition to consumers as when first made, is by at once after churning, cooling it (whether the thin or the thick kind) to below 50° F. and keep it at that temperature until delivered.

We all know that even the best and sweetest milk deteriorates awfully fast if left at a temperature above 60° F., not to speak of 70° F., or more; and therefore we should easily understand how natural it is that buttermilk, in which all germs and especially those producing acidity are very far developed, will spoil and become over sour much quicker.

Yet, it is a common thing that the same dairymen who will give much care to cool their sweet milk, will consider it needless to cool the buttermilk, which is already sour.

As stated in a former letter, a very fine article of buttermilk can be produced from a pasteurized skim milk, if such is properly ripened by adding a good and fine-flavored starter of freshly clabbered whole or skim milk.

Such makes a very smooth buttermilk which, if kept cool, has a better keeping quality, viz., does not so easily become over sour, than that produced from raw milk or cream; neither is such so apt to let the whey separate from the curd, which is the common trouble which befalls people who claim that no buttermilk can be produced as good from separator skim milk as from churned cream.

The trouble is simply that because acidity develops quicker in skim milk than in cream, especially if such is fairly rich, the skim milk needs more care in ripening to avoid it becoming too sour. It takes some practice before you succed.

First, therefore, see to it that your buttermilk is right when it leaves the churn; and then put it in Common Sense coolers with a dasher in, set in as cold water as you have, and preferably in ice water, stir frequently till cooled below 50° or even 40° if you can, and when put in cans for shipping or delivery, have these protected in some way from the outside warm air, until sold. Tell your customers to keep the buttermilk as cold as their sweet milk if they wish to keep it from becoming over sour for next meal. If buttermilk is kept near freezing point in ice or ice-water, you may keep it absolutely fresh and palatable. If the best kind of buttermilk was sold in bottles, ice cold, I am confident you cuold get a good recommedation for such from physicians, as many people can digest such, who cannot at all digest sweet milk.

J. MOLDENHAWER.

Washington, D. C.

Bone Dust for Young Stock.

Touching trials of bone dust, as fed to young stock, the "Societe Nationale d' Agriculture" of France says: The bone-dust employed as an addition to the feeding ration, is known commercially as "*poudre d'os verts*," that is, the powder is produced from what may be described as raw bones simply dried in the open air, and not treated in any way with chemicals. One of the animals experimented upon was a calf 164 days old, weighing about 478 pounds. It received per day about one and one-half pounds of skim milk, three and one-half pounds of oats, three and one-fourth pounds of hay, and three pounds of mangels. On this ration it increased nearly fifty pounds in twenty-four days. To the ration was then added about four ounces daily of bone powder, and in the next twenty-four days the calf increased in weight eighty pounds. Thus there was a gain of thirty pounds in twenty-four days obtained without change of ration beyond the addition of a total of five and one-half pounds of bone powder, which cost three and one-half cents. The bone dust is said to promote digestion and assimilation of the food, and to favor the formation of flesh and fat. Though it is intended to continue the record of this method of feeding, the experimentalists have no doubt of the utility of bone powder as an addition to the rations for young beasts, and indeed, of other animals.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

TAXES ON CREAMERIES AND CHEESE FACTORIES.

Being a former Jefferson County boy, and a reader of your paper, I wanted to ask if there is any other state in the Union where the state law compels a cheese factory, making full cream cheese, to take out an "annual permit" to manufacture. Here in Nebraska we pay to the State Treasury $10 for each creamery or cheese factory.

T. E. G.

Avoca, Nebraska.

We do not know of any legislation, elsewhere, quite as strict as this Nebraska statute, but we are not prepared to say that if the money thus collected is applied to a thorough, official inspection of the factories and incidental instruction, it may not prove a wholesome regulation.

RESTORING BODY TO PASTEURIZED CREAM.

I have been told that there has been a bulletin given out by some of the experiment stations, in which they recount using lime water to thicken cream for retail trade. Can you tell us where we can get this bulletin and if it is practical?

F. E. R.

Whitehall, N Y.

The bulletin referred to is the one issued by the Wisconsin Experiment Station, on the use of calcium sucrate, for restoring the body of pasteurized cream. It can be had on application to the station.

Calcium sucrate is a compound of caustic lime and common sugar, dissolved in water.

When added to pasteurized cream, which has lost its body by heating, the lime compound acts by restoring the thickness of the cream by its action on the casein, and by its causing the fat globules to reunite in groups.

Caustic lime in fine powder or lime water,

both have the same action but the use of caustic lime is not practical, on account of the difficulty in handling it, and the lime water dilutes the cream, as lime is but slightly soluble, one part to 700 parts of water. The solution of lime in sugar syrup was found to solve the difficulty in a practical manner, and enables one to restore the body of pasteurized cream in a thoroughly satisfactory way.

Great care should be used as to the amount of sugar-lime solution added, as too much will cause the cream to become semi-solid on standing, and also give it the taste of the lime, a condition which would result in an immediate loss of custom.

A MASSACHUSETTS RATION.

Enclosed please and $1.00 for binder and pamphlet on raising calves.

Although I have taken the DAIRYMAN for a few months only, I don't see how I could get along without it. I wish it might be in the hands of all dairymen in this section.

Have been particularly interested in the feeding question, and I believe that dairymen in this section need to learn the importance and value of a balanced ration. Will you kindly give me a balanced ration from the following:

Cream gluten meal, $20 to $23; mill feed $18; corn meal $18; mixed hay; cotton seed meal is about the same price as gluten.

Grafton, Mass. T. R. C.

Gluten meal, corn meal and cotton seed meal are highly concentrated feed stuffs, and should be extended or diluted with something much lighter. Nothing is quite so good for this purpose as light, clean, flakey bran. If this is not available, hay or straw may be chaffed fine and used for this purpose. Possibly the "mill feed" might be used, but this is a very indeterminate expression. In the formula which follows we specify bran, but if this cannot be had, the mill feed may be tried. For cows weighing not more than 1,000 pounds, and not past their prime milking period, the daily average allowance—giving the large milkers more and the others less—may be tried.

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
20 lbs. mixed hay	17.16	.96	7.92	.32
6 lbs. bran	5.29	.75	2.32	.18
2 lbs. gluten meal	1.84	.52	.87	.12
Totals	24.29	2.23	11.11	.62

One pound of cotton seed meal might be substituted for the same amount of gluten meal, and if one wanted to feed heavier, one to two pounds of corn meal might be added.

ALFALFA AND BEGGAR WEED SEED.

In HOARD'S DAIRYMAN of Aug. 11, 1899, I saw a lengthy article on "The Florida Beggar Weed," in which article the beggar weed is very highly recommended. Also another article speaking of the great superiority of alfalfa as a stock feed. Where and at what price can I procure seed of both plants?

Columbus, Ga. N. R. K.

You can obtain alfalfa seed from any dealer in seeds. We cannot say where Beggar Weed seed can be obtained, but you can probably obtain information on the subject by writing to the Florida Experiment Station.

ENAMEL FOR WET WALLS.

In reply to an inquiry on page 509 of the DAIRYMAN for an enamel for wet walls, Mr. Monrad sends us the following:

As to that inquiry, it seems to me that I have read somewhere that the addition of a certain amount of "kaolin" to common paint will do just what J. M. on page 509 asks for. J. MONRAD.

SERVICE FOR YOUNG BULLS.

In answer to a delayed inquiry, by a Dakota subscriber, who has a valuable young Jersey bull from Hood Farm, we would say that a single service every second week ought not to injure a well developed yearling; indeed, in case of necessity, we would not hesitate to use him more frequently, say one service every ten days.

WAGES OF BUTTER MAKERS.

Kindly let me know what salary a first-class butter maker would demand. We prefer a graduate. C. A.

Spanaway, Wash.

It depends on the amount of work to be done and the responsibility which he assumes.

It may be anywhere from $40 in a small creamery, handling but little milk, to $100.00 per month in the largest creameries.

Perhaps $60.00 per month is a good average.

SUPPLEMENTARY FEED ON PASTURE.

We have answered this question so often, that it would seem regular readers ought to be pretty familiar with our views, but one of our new readers repeats the inquiry, and we may say briefly for his benefit and that of others, that when pasture is abundant and fresh, there is nothing better and nothing generally so cheap as good hay. But where the pasture grass becomes short and dry and scanty, recourse must be had, not only to hay or silage or some soiling crop, but to more or less grain.

Bran is good in such cases, and where corn is cheap, some ground corn may be added. Gluten feed is also giving good results.

A MISSISSIPPI RATION.

Please give a balanced ration of the following, for Jersey cows: Cotton seed hulls $3 per ton, cotton seed meal $16, wheat bran $17, and corn meal $20.

Mississippi. J. M. T. HAMILTON.

Mr. Hamilton is only a recent reader of HOARD'S DAIRYMAN, and is therefore excusable in large degree for not having something better than cotton seed hulls as roughage for milch cows. That cows will eat these hulls, that they will sustain life, that they may be useful and even economical as a part of the ration, is cheerfully admitted; but they contain only a meager amount of nutriment adapted for milk making. Posterity has justified the complaint of the ancient Israelites against that Pharaoh who compelled them to make bricks, but would not furnish them material necessary for that purpose; in like manner the milch cow prefers an unanswerable indictment against her owner when he does not provide her with the elements in her daily ration that she is expected to return in her milk. We may not understand all the intricate mysteries of digestion, assimilation and metabolism whereby the cow manufactures milk, but investigations have gone far enough to show that the solids in the milk come from the solids in the feed, and that there is no other source than the protein in the feed, from which she can derive the casein in the milk.

Cotton seed hulls are not only remarkably low in protein, but they are very difficult of digestion—about on a par in these respects with wheat straw. They may be fed in limited amounts with satisfactory results, but they should not constitute the only roughage. Good silage and hay of some description must be supplied for winter forage and for the seasons of summer drouth, before we can reasonably demand paying returns from the milch cow.

A good Jersey cow in Mississippi when in fair flow of milk (say, twenty to twenty-five pounds daily) will require from twenty to twenty-two pounds of dry matter in her daily allowance of feed and this dry matter should contain approximately the following amounts of digestible nutrients:

Protein	2.25 pounds
Carbohydrates	10.00 pounds
Ether extract (fat)	.65 pounds

The problem before us is to find these digestible nutrients in the feeds named by our correspondent, and maintain a wholesome and healthful correspondence between the roughage and the concentrates. The stomach of the cow is a capacious affair, designed by nature to work over large quantities of coarse feed, which supplied the requisite material for the maintenance of herself and offspring. The modern milch cow must do more than this, and hence must have more feed, We must therefore have bulk enough to distend the stomach, otherwise it cannot properly perform its functions—and must incorporate in this bulk, richer feeds.

It has been found expedient, under ordinary conditions, to have about two-thirds of the dry matter in roughage or coarse feed, and the balance in concentrates (grain).

In making up a trial ration, we can reject the corn meal because of the price, and because it does not furnish as large a per cent of protein as bran, and the following comes as near our requirements as is possible:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
15 lbs. cotton seed hulls	13.33	.05	4.97	.26
5 lbs. bran	4.41	.63	1.93	.15
3 lbs. cotton seed meal	2.75	1.12	.51	.27
Totals	20.49	1.80	7.41	.68

Notice what a vast improvement it would be to take away some of the hulls and add cow pea hay.

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
5 lbs. cow pea hay	4.47	.54	1.93	.06
10 lbs. cotton seed hulls	8.89	.03	3.31	.17
Grain as above	7.16	1.75	2.44	.42
Totals	20.52	2.32	7.68	.65

Or we may use crab grass hay as follows:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
10 lbs. crab grass hay	8.24	.57	3.97	.14
5 lbs. cotton seed hulls	4.46	.02	1.66	.09
Grain as before	7.16	1.75	2.44	.42
Totals	19.86	2.34	8.07	.65

A CALIFORNIA RATION.

Will you please formulate for me a balanced ration from the following feeds: Pasture, Bermuda sod grass. Have crushed barley, $17 per ton. Bran is worth $17 per ton, middlings $19, oil meal $40, cotton seed meal $40. Would it be advisable to sell the barley and buy a substitute. Cows weigh 900 pounds. E. M. L.

Lockeford, Cal.

We cannot give a complete formula for a ration where cows are at pasture, because of the impossibility of estimating the amount of grass they may be able to get. It is always necessary for the feeder to be careful in feeding and see that each cow gets all she wants and no more. This watchfulness is doubly necessary when cows are at pasture. We would advise mixing by weight three parts bran, two parts crushed barley and one part cotton seed meal and feeding from six to twelve pounds of this daily, apportioning the amount according to the capacity of each cow to respond. Having barley, there is also undoubtedly barley straw and some of this may be fed.

CLOVER QUESTIONS FROM VERMONT.

1. Is it so late that crimson clover sown alone would furnish any feed for cows this fall?

2. How much seed shall I use to an acre?

3. Am I so far north that I cannot raise alfalfa?

4. If not, when must I sow it and with or without a catch crop? I. W. G.

East Calais, Vt.

1 and 2. With favorable conditions for germination, which include the preparation of a good seed bed as well as sufficient moisture, it is probable that crimson clover, sown at any time prior to September first, would furnish very considerable fall feed. But to make assurance of fall feed we would recommend sowing with barley or oats, using ten to fifteen pounds of the clover seed with two bushels of the grain per acre.

2 and 3. Alfalfa is becoming a favorite crop in many places where a few years ago it was considered impracticable to grow it.

From recent experience, it would seem probable that it would do well in many Vermont localities, but in all cases where new crops are to be tried it is prudent to experiment first in a small way. That is just what the editors of this paper are doing with alfalfa the present season. The popular directions are to sow alfalfa without a nurse crop on ground free from weeds, and thoroughly prepared. Alfalfa has the reputation of being a very tender plant when young, and hence needs best conditions. The present season in this vicinity has been exceptionally propitious for seeding, and our best success has come where the alfalfa was sown with oats and the oats cut very early for hay. The alfalfa has come on beautifully since the oats were cut and is now an excellent stand, showing a good many blossoms.

A NEW YORK RATION.

What grain would you feed to get the best results from, counting cost of feed? Wheat bran, $18 per ton; wheat middlings, $19 per ton; cotton seed meal, $25 per ton; oats, 40c per bushel, unground. Will have ensilage enough to feed my fresh cows and those not more than four months in calf, twenty-five to thirty-five pounds per day; good oat straw and mixed hay, clover and timothy, got in in shape. Object, cream.

My cows are grades of Durham, Jersey and Ayrshire—all of them heavy milkers and range from 1,000 to 1,100. They will be in all periods of milk, some fresh every month.

Clinton Co., N. Y. H. T. F.

The main points in feeding a milch cow are (1) to satisfy her appetite; (2) include enough protein to enable her to reach her full capacity as a milker; (3) secure these feeds at least cost.

The last point rules out oats very decidedly, and middlings with less emphasis. The second point suggests the following:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
30 lbs. silage	7.92	.39	4.26	.21
10 lbs. hay	8.58	.48	3.96	.16
6 lbs. bran	5.29	.75	2.32	.18
2 lbs. cotton seed meal	1.84	.74	.34	.18
Totals	23.63	2.36	10.88	.73

The above formula gives sufficient protein and ether extract, but is deficient in carbohydrates, and the amount of dry matter will not suffice to fill the stomachs of these large cows. Therefore add what oat straw they will eat.

CREAM QUESTIONS.

A dairyman at Valcour, N. Y., asks what per cent of fat is required for "standard" cream. The answer is that the standard varies with the locality. In some places sixteen per cent fat is accounted standard cream and in other places the requirements are from twenty to twenty-five per cent. Perhaps twenty to twenty-two per cent is the more universal requirement.

***

He also asks how much more butter, cream containing twenty-eight per cent fat will make than cream containing 22.5 per cent fat. This would be a purely mathematical problem, if we assume that the churning is equally exhaustive in either case, but this is unlikely, because, as a rule, the richer cream churns out cleaner, and in any event, there is less buttermilk for the percentage of loss to apply to. It is therefore quite safe to estimate that the twenty-eight per cent cream will yield twenty-five per cent more butter than the 22.5 per cent cream.

***

His third question is what per cent of fat must cream carry to yield one pound of worked butter from two quarts of cream. That amount of cream will weigh a fraction over four pounds, and as it requires .85 of a pound of fat in the cream for each pound of worked butter, it is approximately correct to say that two quarts of cream testing twenty-one per cent fat will yield one pound of butter.

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By Prof. H. L. Russell.]

Second Series, No. XXIII.

BACTERIA AS SOIL MAKERS.

If one lives in a country which has not been covered, in by-gone ages, with that mantle of ice, known as the glacier, he is, doubtless, familiar with the general principles of soil formation. That superficial covering of the rocks known as the sub-soil, was once as hard and enduring as the underlying stone. If one notes the appearance of a vertical section of these layers, as may often be done in a deep railroad cut, they will observe the gradual change from the firm, intact stone below, to the mellow, rich soil above. First, there is to be seen the broken, angular bits of rock that are hard and resistant. Between these is the coarse earth, which above becomes more homogenous, making the rich fertile soil.

While this process of rock-weathering and soil making is generally looked upon as the result of purely chemical and physical changes, still vital actions aid and accelerate the same. In the very earliest stages, when the bare rock is exposed to the action of sun and rain, these lowest of all organisms, the bacteria, are helping on the process of soil manufacture. It seems incredible, that any thing alive could exist, much less grow, in such a situation, but certain forms, as the nitrifying bacteria are able to do so. These germs require, for their nourishment, no prepared food, no organic substance of any kind. Bathed in the carbonic acid, which is present in small trace in the air, they assimilate their nitrogen from the ammonia of the air, and so form the acids which, in part, act upon the rock mass, dissolving the same, and aiding in the weathering process.

The film of organic matter, which they produce, gives conditions that enable the rock-loving lichens to establish themselves; then the mosses, and finally the higher plants, and so, aided by many different forms of life, the enduring granite, as well as the softer sandstone, yield gradually to decay, and soil is slowly formed.

BACTERIA AS HUMUS FORMERS.

The more valuable function of bacteria, as soil makers, comes in the later stages of soil formation. Even after the rock has been ground into powder by the "gnawing tooth of time," it is not fitted, fully, for the function of crop production. The finely ground rock flour may contain the necessary lime, magnesia and iron that has been rendered more or less soluble by the processes of weathering, but before the plant can take these minerals, and build them up into stalk, leaf and grain, other elements must be forthcoming, the most important of which is nitrogen and carbon.

If you look at a vertical section of soil, some feet in depth, it is at once apparent that the superficial layer is sharply contrasted from the lower. The one is black or brown, as the case may be; the other changes in appearance, with the character of the underlying rock. This upper layer derives its different color and appearance from the action of living forces. It is the humus, or layer of vegetable mold. It represents the scene of labor into which the soil bacteria largely enter. The organisms that work over the refuse of organic existence, be it vegetable or animal, finds on the surface of the soil, favorable conditions for humus formation. Compacted by pressure from above, heated from the absorbed rays of the sun, moistened with the water that is precipitated as rain or snow, and held in this material as if it were a great earth sponge, this mass of dead organic tissue yields easily to the attacks of innumerable saprophytic forms, that tear down the complex cell, appropriating what is needed to maintain themselves, and throwing out the remainder as a waste product, which material may serve in turn, for other forms to feast on, until, finally, the wide spreading tree, or the pulsing brain of an animal or man may be given off to the elements, in the form of invisible gas.

The formation of humus represents not a single process, but a many-sided, complex, process that varies greatly with the conditions. One vegetable mold of the forest, the acid and antiseptic peat bog, into the depths of which animals may have fallen centuries agone, to be unearthed, unchanged at a later date, the rich black muck of the lowland moors, all these are characteristic forms of humus. They represent organic matter on the way to be utilized by succeeding generations of plants. In the form of humates and organic or albuminoid nitrogen, the carbon and nitrogen are held in reserve to be given up slowly to each succeeding crop by the gradual process of decay.

What a wise provision is this! How like a savings bank that pays a small annuity, but does not permit of the impairment of the principal. So long as the supply of humus is maintained, so long will the needful elements be gradually given to the growing plant. Rob the soil of its humus and you destroy at once its crop producing power. It used to be thought that it was necessary for the humus to be completely decomposed, before it could again enter the living plant, but recent discoveries indicate that the plant may take more than purely mineral food from the ground. In the processes of decomposition, various organic compounds are produced, some of which can certainly be appropriated by the plant. The composition of plants grown on soils rich, as well as deficient, in humus, tell this story. Take the beet sugar plant; on soils rich in organic matter, the yield of sugar is much lessened, as the saccharine matter combined with the absorbed organic matter cannot be recovered.

Besides acting as a store house of fertilizing material, humus exerts a very beneficial effect on the soil in other ways. Its power to retain moisture is very marked; where present in quantities, it acts as a sponge, absorbing and holding immense quantities of water, yielding this up gradually. The denudation of our large forest areas, and the consequent destruction of the humus, permits the water precipitated as rain to run off quickly, instead of being held as it used to be. The sudden and tumultuous freshet has replaced the gradual rise of many of our river systems. Such processes not only promote erosion but they tend to lower the ground water level, because a less amount of the water that falls as rain, percolates into the soil. The desolated, gullied fields of the south, testify what the soil will become, if the humus content is not conserved.

Then again, the texture of the soil is profoundly affected by the amount of humus that it contains.

It lessens the cohesion of soil particles, and therefore makes the soil more friable, an improvement that is of especial value in clay soils, that have a tendency to bake.

The formation of humus, being dependent upon the action of biological forces, is hastened or accelerated by the effect of external conditions. Moisture and temperature are the two most important factors that determine the rate of change. Abundant moisture and a warm soil hasten greatly the processes of decay.

While the formation of humus is a necessity in a soil, from the standpoint of agricultural practice, still the presence of too much organic matter impairs its fertility, because it stops other necessary processes. As humus is always acid, such soils may become so sour that proper plant growth cannot occur.

Another of the important soil processes is that of nitrification, in which nitrates are formed from the organic ammonia as in humus. If, however, the soil is surcharged with humus, the bacteria of nitrification cannot properly develop and therefore the fertilizing organic matter remains unutilized, because unavailable.

Salt and Salting Cheese.

WHY NOT USE THE BEST SALT?

Ed. Hoard's Dairyman:—While most butter makers have learned that it pays to use the best salt they can get hold of, there seems to be a tendency, among most of the cheese makers, to buy the very cheapest they can get even the coarsest barrel salt.

This is all wrong. Such salt is uneven, and, as a rule, full of rust, dirt and pan scales (gypsum.) Often it contains a small percentage of lime (which is harmless) calcium chloride (which attracts moisture and causes the salt to lump,) and magnesium chloride (which gives the salt a bitter taste.)

Too coarse and uneven salt does not dissolve quickly enough, and, what is more, dissolves unevenly, and this fault we can easily detect.

Rust and dirt specks may be detected, by dissolving the salt in a glass, or, better still, a high cylinder full of water, when the dirt will show at once, either as a sediment on the bottom of the glass, or as a scum on top.

As regards the absolute chemical purity of a salt, which salt agents often boast about, it plays but very little role, as long as the impurities are not present in too large quantities, especially the magnesium which imparts a bitter flavor to it. Most of our so-called dairy salts are pure enough for all practical purposes.

But it is said that some manufacturers simply grind up coarse salt, and then the pan scales cannot be detected, and for that reason we should not be satisfied with the fineness of the grain and the name of dairy salt, but should protect ourselves by buying *those brands only that have stood the test of years.* There are many refineries where the product seems to be all right to-day and all wrong to-morrow. It requires experience and an expensive plant to make a uniform good salt, just as it does to make a uniform good cheese.

But—and a very large B-U-T, if you please—granted that we have bought one of the very best salts in the market, we must still test it, not only for possible dirt accumulated in transit (when shipped in poor bags,) but also for *taint.* Salt will absorb odors very easily. I know of a case where a car load was spoiled by being shipped in a cattle car not properly cleaned and deodorized. Hence, we must buy of a dealer who understands this, and keeps his stock in a clean place.

Mr. H. B. Gurler, who once had salt tainted by storing in a shed next to a stable, recommends in his "American Dairying," to test salt for taint, by dissolving it in warm water, when a nose in fair working order, will detect it.

It is a peculiar fact, that a higher percentage of the creamery butter makers read and study, and keep "up to date," by subscribing to Hoard's Dairyman and other dairy papers, than do the factory cheese makers. Possibly this explains why they do not seem to have learned that the best salt is none to good for cheese as well as butter.

Another reason, I believe, is in the common system of farmers paying the cheese factory owner so much (or rather so little) per pound for making, leaving it to him to buy the supplies. As there is strong competition, the price of making is reduced, and he tries to save himself, by buying the cheapest of supplies. It is true, he guarantees his cheese to sell at "market" price, but the farmers overlook the fact that the other factories work on the same principle, so that the system has the tendency to reduce the quality (and "market" price) all round, and that they—the farmers—have to suffer the loss in the end.

It seems to me so evident that it pays to buy good salt for cheese, (as well as the best rennet and coloring,) that it needs no arguments.

THE OBJECT OF SALTING CHEESE.

In discussing the quality of the salt used, it may be of interest to take up the question of applying the salt to the cheese; doing so, we should consider the reason why we use salt at all.

First of all, it is used as *flavoring*, and as such only is it used on cheese intended to be eaten at once; and in this connection the detriment of an inherent, bitter flavor or absorbed taint in the salt, will be self-evident.

The second object is to use it as a preservative, arresting or rather delaying, and modifying the fermentation in the cheese.

"He Laughs Best Who Laughs Last."

A hearty laugh indicates a degree of good health obtainable through pure blood. As but one person in ten has pure blood, the other nine should purify the blood with Hood's Sarsaparilla. Then they can laugh first, last and all the time, for

Hood's Sarsaparilla
Never Disappoints.

The third object—and by no means the least important—*is to absorb moisture from the curd*, which will also reduce the fermentation. Too much salt will make the cheese too dry and crumbly and delay its ripening too much, but, up to a certain point, salt acts on cheese as it does on butter when we have poor milk—like acid and charity—"it covers a multitude of sins." It is certain that a sufficient quantity of salt to delay ripening for two or three months, directly or indirectly produces a better cheese.

The best cheese (I refer to Cheddar and similar cheese) cannot be made from a fast curing curd.

Salt has also the effect of hardening and toughening the rind, especially where it is applied from the outside either dry or through a strong brine bath.

There are three systems of applying the salt to cheese: 1. Mixing with the curd. 2. Rubbing the dry salt on the surface of the cheese. 3. Brine salting.

APPLYING THE SALT BY MIXING IN THE CURD.

This is undoubtedly the oldest system and is still the only one used for Cheddar cheese. As soon as the curd is ripened enough (developed sufficient acidity, as shown by the hot iron test) and subdivided fine enough by the mill, the salt is mixed with it and will soon be dissolved by the moisture attracted from the curd, and a circulation is at once established where the thin whey passes out and mixes with the heavy brine which enters the curd. The result is a reduction of moisture (and weight) just in proportion to the salt used.

This will explain the necessity of having a salt of uniform grain so as to get a uniform abstraction of moisture from the curd. It also explains the necessity of mixing the salt and curd carefully, and for that reason I favor a rather coarser salt than for butter. Very fine salt will mush, like fine sugar on berries, and be more difficult to distribute evenly.

There is, of course, quite a quantity of salt lost in the whey expelled. To use the word "lost" is perhaps not quite fair as that part of the salt used has fulfilled its mission by drawing out the whey in which it was dissolved.

APPLYING THE DRY SALT TO THE SURFACE OF THE CHEESE.

This system is used by makers of various cheese (not Cheddar) and has the advantage of allowing them to control the curing of the cheese, by delaying or hastening the application of the salt. As a rule, the cheese is first allowed to dry for four to five days in a warm room. This starts the fermentation and then the maker regulates it partly with the salting.

It is applied by rubbing it dry over the surface of the cheese and the result is as described above—a gradual absorption of the

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,
67 Main Street, - Cortland, N. Y.

brine with exudation of the whey from the cheese. Before salting again, the moisture not evaporated is wiped off the cheese with a dry cloth. If too much salt is applied to start with, the rind becomes thick and dry and the diffusion of the brine in the cheese is not uniform. The upper side only is salted and when absorbed it is turned and the other side gets a salting; hence the round side gets twice as many applications as the flat ones and becomes, as it needs to be, firmer.

If salted too lightly in the beginning, the cheese becomes soft and is liable to lose its shape. But it will be seen that by slower or quicker application of the salt, the moisture is removed accordingly and the fermentation is increased or decreased. And—if you please—it is possible to repair, to a certain extent, errors before pressing (such as leaving too much moisture in the curd) by a free application of salt.

The application must also be regulated according to the temperature and moisture in the room. It "goes without saying," that too much salt in a dry room will make rind too dry and it will crack.

The progress of the salting may be followed by plugging one of the cheese.

For this system, a fine salt is better than a coarse one, and a salt mill with which to crush it very fine belongs to the inventory of the cheese factory.

SALTING IN BRINE.

This system has become more and more popular, and it is said that the cheese thus salted will absorb only a certain amount of salt from the brine, and this can only contain 26.5 per cent salt. It is evident that the circulation of brine into the cheese must cease as soon as the whey in the cheese has attained the same specific gravity as the brine.

The brine is made with a surplus of salt and salt is sprinkled on the upper side of the cheese which is turned twice a day. The cheese is generally left to dry a day or two after leaving the press and it takes from two to four days to finish the salting. A soft cheese will absorb the brine quicker than a hard one, and no fixed rules can be laid down.

Dr. Fleischmann made some experiments with Swiss skim cheese showing a loss of weight by salting as follows:

		I		II
	% Loss.	From Press	% Loss	
Weight from press	13.35	14.60		
Weight after 24 hrs. in brine	13.00	2.62	14.20	2.74
Weight after 48 hrs. in brine	12.80	4.12	14.00	4.11
Weight after 72 hrs. in brine	12.60	5.62	13.08	5.48
Weight after 96 hrs. in brine	12.55	5.99	13.75	5.82

Two experiments with full cream cheese showed similar results,—between five and six per cent loss in weight in four days.

It appears from these experiments that most of the salt is absorbed and whey expelled in the first two days, and that it is done in a uniform manner. The rind is very firm as the cheese is taken out having absorbed an excess of salt, which is distributed later, making it more elastic.

This system gives altogether a much nicer rind than by the other two, and deserves more than a passing thought.

IS BRINE SALTING POSSIBLE FOR CHEDDAR CHEESE.

Dr. Kleurge, from whose book I have drawn part of the above information, finishes by saying about salting the curd: "While this—rather crude system is used as yet for certain kinds of cheese (referring to Cheddar) it is presumably because no one has taken the trouble to try a better one, like the brine system."

With a slight modification in the making, by developing a little less acid before going to press, it seems to me also that it may be possible to adopt the brine salting for Cheddar, and it would certainly be worth while for our Experiment Stations to take the matter up.

To change it without modifications, as Dr. Kleurge seems to suggest, would not do, and a series of experiments will be needed to get at the right way.

Possibly a compromise might be the thing, so as to apply half the salt in the curd and finish it in a brine bath. In any case I hope to see this question investigated carefully.

J. H. MONRAD.

Cow Comfort.

ED. HOARD'S DAIRYMAN:—With interest I read L. W. Lighty's article, Cow Comfort in Summer, and on the comfort of the cow during the hot months and fly time, depends, largely, this year's production.

Thinking men have adopted stabling during the heat of the day, and pasturing at night. Mr. Tilson, of Tilsonburg, Ontario, was one of the first to adopt this method, and he found it not only increased the milk flow during the heated term, but wonderfully increased the fall and winter flow, above all former years.

To increase the flow of milk, and not to re-establish a decrease, is successful dairying.

This method has proved so gratifying to us, that our experience may not be out of place. Cow comfort the year round is our motto, and the requirements are sunlight, pure air, thorough ventilation.

Our stables are arranged with southern exposure, 3×6 feet windows six feet apart, giving the cows abundance of sunlight all day long. The autumn, winter and spring sunshine are among the requirements of successful dairying, as much as the exclusion of the burning sun of July and August.

When the summer season advances, and fly repellents no longer assure the cow's comfort, we cover the windows on the outside, from the top down to within six or eight inches of the bottom, with cloth or shutter, leaving the window opened at the top, by this means giving free access of air on the inside. We cover the windows from the bottom nearly to the top opening, leaving the stable nearly dark. The cows are fed and milked in the morning, and turned out. The stables cleaned, bedded, and the cows returned at nine o'clock a. m., remaining until after milking at night, when they are turned out to pasture until morning. This relieves them of the fly nuisance entirely, and a friend remarked, "their appendages would drop off from disuse."

The result is, no preceptable shrinkage of milk since June, and stock in best possible condition for fall and winter production. In addition to this treatment, we feed our cows three hundred and sixty-five days in the year. They receive their ensilage and grain ration in proportion to the succulence and condition of their pasture, combining comfort, care and feed.

Marion Co., Ind,

Feeding Young Pigs.

Prof. Thos. Shaw recommends the following supplemental feed for young pigs where they do not get feed enough from the sow: If there is skim milk on hand, partition off a place in the pen where the dam is, if necessary, but which she cannot reach, and there, in a low trough, feed some skim milk as soon as the pigs will drink it. As soon as they take it freely, feed them a slop of shorts and milk. Then give them a little oats or corn stewn on the floor in addition to the slop. Feed the slop so that it will not become stale at any time. If there is no skim milk at hand, a thin slop of shorts and water is next best, presumably a little warm if the weather is cool. But when the trough room is ample, young pigs may have their food supplemented by allowing them to eat with the dam at will. The same kinds of food that are best suited to provide an abundance of good pure milk from the dam, will alone provide the right sort of feed for the pigs. But the trough should be low and one or more planks should be in front of it, so that the little pigs can easily get into it. And care should be taken not to feed much bran or the hulls of oats to the sow when the pigs are learning to eat, as such food is too coarse for the digestion of the little pigs. It is surprising how soon they will learn to eat thus along with the dam. Take it all in all there is perhaps no better mode of management than that just subscribed for average conditions. It is the least labored. It answers very well and forces one to be cautious as to the character of the food given to the dam.—*Indiana Farmer.*

Regulating Test Bottles in Vermont.

Act No. 81 of the Vermont laws of 1898 entitled, "An act for the protection of dairymen, and relating to testing milk and cream," provides that all glassware used in dividend making, whether by Babcock or other tests, at creameries or cheese factories, shall be tested as to its accuracy, and if found correct, indelibly marked as proof thereof. The law provides further, that every person using the Babcock test in dividend making shall secure a certificate as to competency.

This law took effect February 1st, 1899. The latter part of December, 1898, regulations were issued by the superintendent of the dairy school of the University of Vermont and State Agricultural College, in accordance with this act, and sent so far as possible to all creameries and cheese factories in Vermont. Up to August 1st, there have been tested at the experiment station, 9,564 milk and cream bottles, and 1,515 pipettes. Nearly four per cent of the old bottles in use at the time of the enactment of the law, were found to be incorrect, but with the new glassware that has since come into the state, this percentage has materially decreased.

Correct apparatus is etched with the characters "Vt. Ex. St." on the neck of the bottle or bulb of the pipette. Tested glassware can be obtained direct from the large dealers in dairy supplies in the state.

Two hundred and forty-one certificates have been granted to persons to use the Babcock test. Failures have occurred in thirty-one cases, and eighteen examinations are now pending.—*Chicago Produce.*

Anti-Aborsio.

At a Farmers' Institute held at Gilboa, Schoharie Co., N. Y., on March 18th and 19th, 1896, the following inquiry was found in the "Question Box," and was answered by H. Van Dresser, State Lecturer at Farmers' Institute, also President of Breeders' Association of the state of New York.

Question—What is known of Anti-Aborsio as a preventive and cure of abortion in cows; also as a disinfectant?

Answer—"Abortion is a terrible disease. In my travels I find it prevailing throughout the entire Union at a loss to the farmers of many millions of dollars. I am glad that a remedy has been found. I speak from personal knowledge and the knowledge of such men as Congressman Wilber, Senator Brown and McLaury Bros., all of whom are extensive breeders of fancy cattle, and many more who are using the remedy with perfect success. One man at my place had eleven cows abort; sent and got one gallon of Antiaborsio which stopped it at once. About six weeks ago I met Henry L. Wardwell (an importer of fancy cattle) at a meeting in New York City of the Jersey Cattle Club. He announced at the meeting that he had used this remedy and that it had proved a perfect success. In my travels I have met many that have used it, and to my personal knowledge do not know of a single failure. If there is one in this room who has used it and found it to be a failure, please arise." No one arose. "I have used this remedy and found it to be a perfect success, and am now using it in my poultry house as a disinfectant. Everybody should use it and it should be universally used throughout the United States.

I do not own any part of this remedy and am not interested in it in any way except in the interest of the farmer."

IS YOUR HAIR TURNING GRAY?

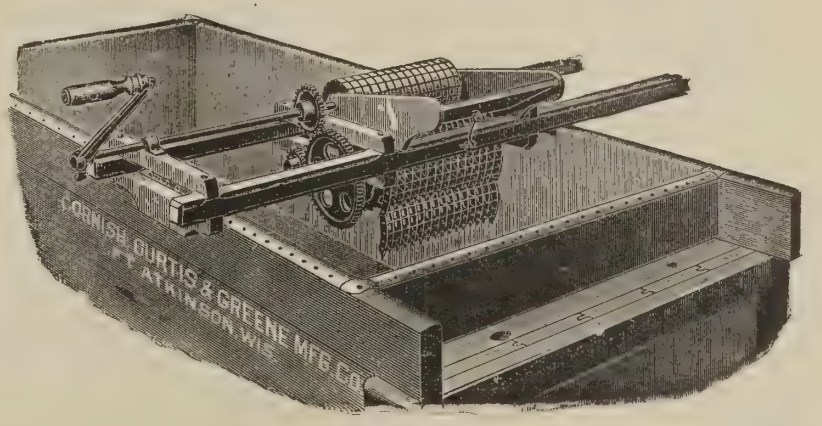
What does your mirror say? Does it tell you of some little streaks of gray? Are you pleased? Do your friends of the same age show this loss of power also?

Just remember that gray hair never becomes darker without help, while dark hair rapidly becomes gray when once the change begins.

Ayer's Hair Vigor

will bring back to your hair the color of youth. It never fails. It is just as sure as that heat melts snow, or that water quenches fire.

It cleanses the scalp also and prevents the formation of dandruff. It feeds and nourishes the bulbs of the hair making them produce a luxuriant growth. It stops the hair from falling out and gives a fine soft finish to the hair as well.



We have a book on the Hair and Scalp which you may obtain free upon request.

If you do not obtain all the benefits you expected from the use of the Vigor, write the Doctor about it.

Address, DR. J. C. AYER, Lowell, Mass.

SHORTHAND Book-keeping, Penmanship, 64-page Illustrated catalog free. Board and tuition reasonable. Situations for Graduates. Address, D. L. MUSSELMAN, President, Gem City Business College, Quincy, Illinois.

Kasper Rotary Curd Mill.

The demand for a large capacity curd mill for cutting curd into cubes has induced the inventor to bring out the Kasper Mill. In construction the mill consists of a rotary cylinder made of knives in the form of cubes. Against these knives a wooden roll revolves with indentation to fit the knives of the cylinder; the curd being fed into the hopper is forced through the openings in the cylinder by the wooden roll. The cylinder is made in three sections hung on hinges, and, as it revolves, each section as it comes to the lower part of the cylinder, opens and allows the curd to drop into the vat, the section closing again as the cylinder revolves.

It is estimated that the curd from 7,000 lbs. of milk can be cut in from 7 to 10 minutes. The mill operates easily, being light running and adjustable to either hand or belt power. Simplicity of construction, durability and ease of cleaning are some of its principal features. All parts being galvanized or tinned prevents rusting. Weight of the machine complete is about 38 pounds. List price, $25.00

The General Purpose Cow.

A Competent Witness Describes Her.

In a personal letter to one of the editors, a friend out in Oregon writes as follows:

"It is about time some of us acknowledged the receipt of favors from you, in the shape of the DAIRYMAN. Now, I am no dairyman, as you know,—would not know a dairy if I should meet one in the road, unless it should be riding in one or those fine dairy wagons advertised in said paper, yet I enjoy reading much of its contents.

I was much interested in the discussion pertaining to the dual or general purpose cow, but it is clear to me, that none of your correspondents have yet struck upon the true type of said animal. I once knew a man in Texas, who possessed a sure-enough general-purpose cow. This man, during the few hours he could spare from hunting, fishing, and talking politics at the village saloon, cultivated a small patch of cotton, a little corn and a few potatoes, and as he owned no horse or mule, he utilized the cow for plowing the ground and keeping down the weeds. When his wood pile needed replenishing, he'd hitch the cow to the cart, and haul up a "jag" or two, and when the roads were muddy, he'd saddle and ride her to town.

In the meantime, the cow would furnish milk, butter and buttermilk for the family, and hunt her own forage on the range. More than this, when this man would go to Arkansas to see his "wife's kinfolks," which was upon the arrival of each new member of the family, the cow was used as motive power for the trip.

This cow had no pedigree, but was bristling with points—points that you could hang a hat upon. She also had stomach capacity, and an unsatiable appetite. She would climb oak trees for the leaves and branches. If she had such a thing as a pelvic arch, she did not know it; while there was never an escutcheon in the family, and if one had been offered her she would not have known what it was or where to put it.

She was, in fact, just a plain, everyday, Texas long horn; a jack at all trades, and master of none; was of but little use for milk, a poor substitue for a horse and of little value for beef—a mere makeshift in any capacity. But this style of cow is now out of date, a back number, and will soon be heard of no more in the land."

The illustration on another page in this issue, confirms the conclusion of our correspondent, by showing that even in Texas there are true special-purpose dairy cows, and the neighboring Republic of Mexico is to be congratulated upon securing such animals as are there depicted.

What Made the Silage Spoil?

ED. HOARD'S DAIRYMAN:—On opening my silo, 12×28, last July, I had to throw out about twelve or fourteen feet of ensilage before my cows would eat it. Around the edges it was rotten, soft towards the center. It was sour, but had a good color. It smelt very bad. This year it was the same way, but not so deep. I threw out five or six feet before ensilage was good. My corn was all right when I put it in. The first time I filled it I began on Saturday and finished on Monday; last year I filled it in one day. I had two and three men in silo at time of filling. We tramped the edges only. I wet the top thoroughly after I finished and would tramp it down every day or two.

I am confident it is not the fault of silo. Silo is stave, tongue, and groove, and will hold water. My larger silo, 16×34, keeps ensilage perfectly. Some little spoils around the edges for three or four feet, but after that it is as good against the stave as in the middle. My silos are exactly alike. Would like to know what you think the trouble is.

Dickerson, Md. N. W.

Of course, if the two silos were treated exactalike it is impossible to say what caused so much waste in one, when there was so little in the other. The only explanation we can think of is that the wetting applied so soon after the silos were filled, reduced the temperature in the small silo more than in the large one. Had the wetting been delayed for a day or two, or until the top layer was heated up to about 120 degrees, perhaps the result would have been different. The extra tramping after filling, might have been injurious in a similar way. We do not think it advisable to break up the "sealing" on the surface.

Using a Separator.

ED. HOARD'S DAIRYMAN:—In your issue of August 11th, F. S. Combs, of Annapolis, Md., asks for information in regard to the richness of the milk. As to the first I am unable to say.

2. His speed is too low or the skim milk outlet is partly closed by improper cleaning.

Do not tamper with the float or other adjustment. See that all tubes leading in and out are clear and you will have no more trouble with your cream if the proper speed is attained.

As to a cow's giving richer milk in the morning than at night, I believe to be because she gives a little more milk at night than morning, the amount of butter being the same. It is so with me. A. READER.

Zenobia, Ill.

Cut or Shredded Ensilage.

The shredder has come into very general use as an implement for chopping up dry corn fodder, and is largely superseding the fodder cutter. Dry stalks when torn into long, thin shreds are much easier to handle than when cut up fine. It is the general belief that cattle eat the stalks better when shredded than when cut. The square, sharp edges of heavy stalks which we get in cutting are avoided, and cattle do not get sore mouths from the shredded fodder, as they occasionally do from eating cut stalks.

E. S. Powell, in the *Country Gentleman*, says shredded fodder makes much better bedding, because it is softer and longer. Cattle do not eat the shredded stalks any cleaner than when they are cut fine. At least such has been my experience, continues Mr. Powell. What they refuse to eat is better for bedding, and is easily swept out behind the mangers. But for putting the corn into the silo, I like the cutter much better than the shredder. Last fall we tried the two methods. In one 190-ton silo the corn was cut into half-inch lengths. An eighteen inch cutter with an eleven-horsepower engine and a fifty foot carrier handled the corn easily, and as fast as four men could work on wagons and round the machine. After filling this silo we swung the carrier round to another silo of the same size, and put in the shredder head in place of the knives.

While the engine had an easy time of it before, we found that with the shredder it required all the power available, and greater care in feeding so as not to stop the machine with a big armful, which would have gone through the cutter with only a groan. The shredded corn came out so loose and light that it was necessary to put a third more speed on the carrier in order to take care of it.

The shredded corn filled up much faster, but after the second day's work it seemed apparently to settle as fast as we kept putting in. As there were no scales on the place, and we did not have enough corn to fill this silo full, there was no way of closely comparing which of the two methods would allow the most corn to be put in the silo. But figuring it out from the number of loads and the acreage, none of us could see that one method had any decided advantage over the other in this respect. I have heard it stated that a silo would hold one-third more of shredded than of cut corn, because the shredded corn would settle firmer; but from our experiments, I doubt if there is as much as ten per cent difference, if there is any, in actual results.

The shredded ensilage was opened and fed first. There was less of it spoiled on top than of the cut, but not enough to make much difference. This was undoubtedly due to the fact that the one silo was opened in November and the other in March. The shredded ensilage we could handle nicely with a fork; so we could the other, if the tines were close together. The shredded ensilage does have an advantage over the cut in handling, but that is the only advantage we could see for it. The feeding is the crucial test, and in this the cut ensilage was superior. It was sweeter and brighter in color, and the cattle ate it with less waste. The long, fine shreds of the heavy stalks were not eaten as clean as the cut pieces. For dry fodder, I think the shredder is to be preferred; but for ensilage, I much prefer to use the knives.

FILLING THE SILO.

We have found that the riper we can get the corn before putting it in the silo, the better we like it when it is taken out. Last year we had some experience with frozen corn—our first since we built a silo—and we do not fear a frost nearly as much as we formerly did, as the frozen corn came out apparently in good condition, and we feel that we would risk some frost rather than to cut too green.

We have always cut our corn with the sickle, and so long as we can get men at a reasonable rate, we think it will pay to do so. Four men will cut and load three acres of corn in a day. We have been paying seventy-five cents per day for this work, and we think this is cheaper than it is being done with the harvester. We prefer steam power for driving the cutter, as it is very steady, and we think cheaper than horse power.

We always keep a good reliable man in the silo when we are filling, to keep the corn evenly mixed and spread and to tramp it firmly in every part, especially the corners. To assist in mixing we place something in front of the carriers to catch the corn and let it drop straight down. In this way we get it very nearly right, while if it is allowed to fly from the carriers, the heavy part will go to one side of the pile and the light to the other side. We prefer to put in the corn continuously until the silo is full, then to wait three or four days and fill up again and afterwards to put on a few pails of water and tramp thoroughly each day for a week. The corn will then form as good a covering as is required and we think cheaper than anything we could get on, the waste will not be more than from two to three inches deep over the surface of the silo. It is best to allow the silage to settle for a time, say a month or more, before commencing to feed, although we have fed right along from the time we quit filling. The cattle ate it all right, but we found as we got down to where it was properly cured it was much better. This winter we are cutting hay and straw and mixing it with the silage, a meal ahead, letting it get a little warm before feeding, and so far we are well pleased with the result, feeding meal with it to the milking cows only, the dry cattle doing very well without any other grain than the corn in the silage. You will be pleased with the result if you save a quantity of silage to feed when the pasture fails, say in July and August, and up to the time the corn is ready to put in the silo. We have done so for years now and we get better returns from this method of feeding than from any other we have tried. The cows are very fond of it and are doing well and it is always inside and ready; no hunting for feed in a storm. The silo may be constructed of different forms, and of any material that will combine strength with a texture sufficiently close to exclude air. We think the circular form is the ideal one for ease in packing and preserving qualities; there being no corners in it to require special care in filling, every side presents equal conditions for settling and pressure.

There may be circumstances when it will be advisable to make what is commonly called the square silo, to fit a certain part of a building or to save space. Then I would say, go ahead, build your silo square or oblong to suit the corners. Be particular in filling the corners when putting in the corn, and you will be safe. There are two things to bear in mind when constructing a silo. The silo must be as nearly air tight as possible, and there must be sufficient pressure on the silage to drive out and exclude the air from the cut corn. Right here let me ask you to think of the condition of the corn as it is dropped into the silo and spread about. It is fresh and green, every part with a straight cut edge, and pack as you will there is a very large part of the space occupied with air, something we must get rid of before we can preserve our corn. How are we to do it? We supply the conditions and nature's law does the rest. The necessary conditions are pressure—continuous pressure; the very air that permeates the freshly cut corn assists in its own expulsion by uniting with the elements of the corn and starting a chemical action which causes heat and the air being expanded is forced out. At the same time the corn is softened so that it settles together much more closely than would be possible without this softening process and we believe the corn is at the same time made more digestible by this process. So here the farmer is as usual working hand in hand with nature, making use of nature's law to accomplish the purpose he has in view. Now we must have our pressure ready to act constantly, forcing down and closer together those particles of corn and when this is done our silage cools down and as long as those conditions are maintained our silage is soft. We now see the necessity of pressure and the modern way to get it is to build a deep silo and fill it to the top; and when we say a deep silo we mean not less than twenty-five feet and up to thirty-five feet: Our own silo is twenty-eight feet deep and is giving good results. I do nor think a silo less than twenty-five feet in depth would be satisfactory.—JACOB BRAY, in *Prairie Farmer*.

SAVE THE WHOLE CORN CROP

A corn crop may be profitable without saving the fodder, but it will be twice as profitable if it is saved. The new method of handling corn saves the entire crop. The new way is to run all the corn through our

JANNEY COMMON SENSE Corn Husker and Fodder Shredder

There can be no dreaded "corn stalk disease" where fodder is prepared with our machine. You can make a great deal of money husking for neighbors. Costs less than a third as much as a thresher, but makes more money. Write for catalog.

It husks out all of the corn clean, and shreds all the fodder at the same time. Makes clean, healthful food, as the patented screen in the feed elevator takes out all the dust, dirt, smut, etc.

Go to your nearest dealer and see one.

JANNEY MANFG. CO., Box 29, OTTUMWA, IOWA.

Will it Pay to Build a Stave Silo.

ED. HOARD'S DAIRYMAN:—I have about twenty-five head of cattle, including two horses, three or four cows, a lot of two-year-olds and several calves. I have in sight to feed them through the winter, eight acres of oats, about ten tons of oat and pea hay, ten acres of corn, and a quarter of an acre or so, of turnips and mangels. If possible I shall sell some of the oats and corn, Now, would you advise me to put up a *temporary silo*, as I stay on this place only until spring? Will I run risk of losing any considerable part of the siloed fodder—any more risk, that is, than I would run by cutting up and husking in the usual way? My plan is to make a stave silo over a ten-foot hole in the ground, the hole to be uncemented or lined in any way, the silo so made that it may be taken apart and moved (except the hole) to my future home next summer. Is there much loss by freezing in a simple stave silo made outside of any building.

I read often "don't cover the silo." Does that mean no roof at all? Wouldn't rain and snow be a damage and a nuisance? G. L.

Adams, Wis.

We would not advise building a silo for a single season's use, but if the new location in this case is not too far away, we think it would pay to build the silo for the present season and then move the material to the new home.

Experience has shown that freezing does not materially injure silage.

"Covering the silo" is a misnomer for covering the silage in the silo. It used to be thought indispensable to cover the silage with chaff, or green swale grass, or something of that kind, but now as a rule farmers run on some of the corn from which the ears have been removed. Of course some of the top will spoil, but the green cornstalks make about as cheap a cover as one can get. There should be some sort of a roof over the silo. For temporary purposes a few poles across the top covered with straw or marsh hay or anything that will keep out rain and snow, is all sufficient.

An Independent Veterinarian and His Theory of Tuberculosis.

Dr. Edward Moore is a veterinarian who, after long years of notable success on both sides of the sea, has suddenly acquired greatly increased prominence by disputing the commonly accepted belief that tuberculosis is communicable from beast to man. He first publicly attacked this belief in a paper

presented last spring to the Albany County Medical Society, and noticed in these columns at the time; and he has more recently, by an address before the Assembly Tuberculosis Committee (which we printed last week), urged on that body the necessity of great caution in taking for granted that it has been proved that human health is endangered by using either the milk or the beef of tuberculous animals; in fact, he went so far as to predict that it will be found that "where cattle tuberculosis is plenty, human tuberculosis is so rare as to bear no relation to it; that while you are in the thick of bovine tuberculosis, you are practically outside the consumptive belt." If the germ was originally identical, he believes that it has been so modified in each case that it can live only in man, or only in cattle, as the case may be, and dies harmlessly when transferred from one to the other. Everybody must earnestly hope that this view will ultimately prevail. If it does, Dr. Moore will rank as the pioneer in correcting a widespread and most injurious error; and it should be understood that his opinion is entitled to immense weight, considering that he was studying the disease before some practitioners of the present day were out of their cradles, and insisting strenuously on the necessity of isolating infected animals and disinfecting their surroundings, before many people knew anything about tuberculosis in cattle at all, or entertained the faintest suspicion that it was "catching" among the animals of the herd.—*Country Gentleman.*

Weaning Pigs.

A few days before weaning time we are not so particular to have the sows full fed on milk making foods, but are careful not to have them run down in flesh. Dropping off the soft feed, bran and middlings, and adding corn will do this.

Before weaning, the pigs should be well started on pastures of good quality, blue grass or clover both will work no injury. If the sows can be limited on the amount of pasture for a time it will hasten the drying up of the milk. If the milk flow is partially checked before the pigs are taken from the sow it will be much better for the sows, and the danger from caked teats reduced to a minimum.

When separated, leave the pigs in their old runs, and the same troughs, and put the sow in a dry lot or shed. Keep them separated for twelve hours or a day, and not longer the first time, or the pigs may lose their taste for fresh milk and refuse to suck, at the risk of injury to the sows.

Leave them together but a short time and then separate again for twenty-four hours. After this there will seldom any harm result to the sows if the pigs do not suck any more.

While the sows are shut away from the pigs their feed should be a little dry corn with plenty of good, fresh water. If in good shape when returned to pasture they will not need grain in any form.

Before weaning, the pigs should be up to full feed, so that when taken from the sows there will hardly be a perceptible increase in food necessary. The management here pointed out will carry the pigs over this important time without a check in growth.

JOHN M. JAMISON, in *Ex.*

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade, was exceedingly light, only two lots aggregating 6,120 pounds being placed on sale. Bidding opened at 21 cents and both sales were at that figure. The quotation committee, however, announced the market active at 20 cents. The sales reported were:

	Pounds.	*Price.*
Darinda	3,000	21c
Dundee	3,120	21c

The markets for the corresponding week of the three preceding years were as follows:

August 22, '98, 10,680 pounds of butter sold at 18c.
August 23, '97, 12,420 pounds of butter sold at 18½c.
August 24, '96, 49,320 pounds of butter sold at 17c.

The New York market, Monday, was reported steady at 21 cents.

The dairymen of Elgin, Carpentersville and Algonquin have prepared a statement showing the cost of production and the inadequate returns for milk, and after it is signed will forward it to the officers of the Borden Condensing Company asking a conference with a committee before the next contract price is fixed. It is hoped that the organization may result in better prices for milk. Some farmers say that there is absolutely no profit to them under present conditions and should prices not advance they will sell their herds and devote their energies to agriculture, pure and simple. H. C. B.

Elgin, Ill., August 21st, 1899.

DAIRY MARKETS.

ELGIN, Ill., Aug. 21—There were 102 tubs offered; all sold at 21c; committee reported market active at 20c.

CHICAGO, Aug. 21—Butter—Creamery, extra 20c; firsts, creameries 18@18½c; seconds, 15½@16½c; dairies, selections, 17c; No. 1 14c; No. 2 13c; extra ladles, 13½@14c.

Cheese—Full cream, Twins, new, good to choice 9¼@9½c; Young America, 9¾@10c; Swiss, 8@10½c; Limburger, 7@8½c; bricks, 8@9¼c.

Eggs—Fresh, at mark, cases returned, sold at 10½@11c; loss off; cases returned 12½c.

Bran—Offerings small. A car sold billed through at $10.50 per ton.

Cattle—All desirable corn-fed cattle sold actively, with average prices about 10c higher. The best grass Westerns also shaded higher, while undesirable natives and westerns were barely steady. Canning and butchering stock ruled steady. The general trade was active and a good clearance was made. Two loads of 1,633-lbs Short horns sold at $6.60, the highest in many years, and the highest for August since 1884. Two loads of 1,409-lb steers sold at $6.50. Six loads of 1,408-lb corn fed western steers sold at $6.35. Most of the native steers sold at $5.40@6.15; grass western steers sold at $4@5.25; grass western cows and heifers $3.25@4.70, and straight grass Texas, $3.65@4.60 for steers and $3.50 for cows.

MILWAUKEE, Aug. 21—Butter—Creamery, Fancy prints, per pound 20½c; extras 20@20½c; firsts 18@19c; seconds 16@17c; imitations per pound 16@17c. Dairy, selections per pound, 15@17c. Market unchanged with receipts of 6,597 lbs. and a fair trade.

Cheese—American full cream, new, choice to fancy 9@9½c. Brick, new, per pound, choice, 8½@8¾c. Limburger, new, choice, per pound 8½@8¾c. Swiss, New Drum, choice, 10@10½c; Block choice 10@10½c; No. 2, 9½@10. Market steady, receipts, 880 lbs.

Eggs—Fresh, per doz. 11½@12c; loss-off cases returned. Market steady; receipts 294 cases.

FOND DU LAC, Wis., Aug. 21—Offerings 730 Twins and 750 Daisies; demand good, Twins at 9½c, Daisies 9¾@10c.

MUSCODA, Wis., Aug. 21—Offerings to-day 1,422 boxes cheese; market firm; Twins 9⅜c: Daisies 9⅞c.

BALTIMORE, Md, Aug. 21—Butter—Firm. Creamery Separator, extra, 22c; extra first, 20@21c; creamery firsts, 19@20c. Creamery Imitation, extras, 17@18c. Ladle extra, 16c. Western store-packed, 12½@13c.

Eggs—Market firm. Strictly fresh stock, 14½@15c.

ST. LOUIS, Mo., Aug. 21—Butter—Firm. Creamery 17@21c; dairy, 13@17c.

Eggs—Steady; 12c.

BOSTON, Aug. 21—Butter—Creamery, extra, 21½c; western extra, 21c: dairy extra, 18@19c, Imitation creamery, 15c; Western ladle, 14c; print creamery, 22c; box creamery, 21c.

Eggs—Fancy near by 21@22c; choice, fresh, 17c; Michigan extra, 16c; western, 15@17c; fair to good, 14c.

KANSAS CITY, Mo., Aug. 21—Butter—Creamery, 17@ 9c; dairy, 15c.

Eggs—Fresh, 11c.

NEW YORK, Aug. 21—Butter—Creamery, western extra, 21c; firsts, 20c; state extras, 20½@21c; firsts, 19½@20c.

Cheese—State, full cream, large or small, colored or white, choice, 9@10c.

Eggs—State Pennsylvania and western, 17@18c.

PHILADELPHIA, Pa., Aug. 21—Butter—Solid packed creamery, extras, 21c; firsts, 20c; prints, fancy, wholesale, 22c; jobbing, 23@27c.

Eggs—In fair request and firm with moderate offerings of fine fresh stock. Western choice, fresh in free cases, loss off 15@15½c: fair to good. 12@13c.

BALTIMORE MARKET.

BALTIMORE, Aug. 17—Butter—Before the opening of business in this line of goods on Monday morning, the atmosphere was ominous of some disturbance to take place presently in prices, and it was obvious that no purchases of moment would be made, at least of extra separators, at the figures of the previous week; therefore as all the buyers were arrayed against an advance, and all the receivers convinced that there was an enhancement of values based upon substantial reasons, the selling was pretty much confined to supplying the needs only of the day. On Tuesday, when the higher prices had become an accomplished fact, to a certain extent, not, however, to the degree experienced elsewhere, there was more disposition manifested to procure some of the highest grade on the market, before the full force of the general movement would have its effect here; so there was a gentle selling going on, and is now progressing at conservative prices, but to an extent in happy relief of, and sharp contrast with the lazy condition noted in our last issue. It is believed now, that this upward movement marks a permanent advance, or, at least, of sufficient duration to permit an unloading, and if the exporters can continue their orders at the new quotations, there should be a healthy clearing out of summer goods, and encouraging inroad made upon the accumulations of June makes in the freezers. The price fixers in this country heretofore, almost invariably, have not recognized the best thing when they have had it, but have grasped for more money at the risk of cutting off the demand, and have succeeded in accomplishing the latter. Will it occur this year? Gathered cream creameries, imitation and high grade ladles have felt the movement some, but it is not reflected so much in the values; the benefit is rather in the fact that the selling has been rendered easier at about old valuations, and old lots have been gotten rid of that were awful slow sellers. Of store-packed the receipts have been light with grading poor, but for a' that the demand has been active.

Creamery Separator, extras, 20½@21c; firsts, 19½@20c; seconds, 18@19c. Gathered Cream, extras, 18½@ 9c; firsts, 17@18c; seconds, 16c. Ohio, extras, 18½@19c: firsts, 17@18c; seconds, 16c. Imitation, extras, 16@17c; firsts, 15c; seconds, 14c. Iowa & N. W. Ladle, extras, 15c; firsts, 14c; seconds, 13c. Ohio & Indiana Ladle, extras, 15c; firsts, 14c; seconds, 13c. Ohio Storepacked, extras, 12½@13c; firsts, 12c. W. Va., extras, 12½@13c; firsts, 12c. Creamery Blocks (2 lbs.) extras, 23c; firsts, 22c; seconds, 21c. Creamery Prints, (½ lb.) extras, 23c; firsts, 22c; seconds, 21c. Md. Va. & Penn. Prints, extras, 19@20c; firsts, 18c; seconds, 16@17c.

Eggs—Our market rules firm and strong under continued light receipts. There is a quick demand for all choice to fancy stock, and supplies of this kind are kept well cleaned up at full prices, 14@14½c. Stock of doubtful quality is not so eagerly sought after.

Cheese—Receipts of cheese continue rather light; demand good for the season; market firm as quoted:

New York State Cheddars, fine, 10@10¼c; choice, 9¾@10c: fair, 8¾@9c. Flats, fine, 10½c; choice, 10@10¼c; fair, 9@9½c. Small, fine, 10¾@11c; choice, 10¼@10½c; fair, 9¾@10c. Ohio Flats, fine, 9¾@10c; choice, 9¼@9½c; fair, 8¾@9c. Picnic, fine, 10@10¼c; choice, 9½@9¾c; fair, 9@9¼c. Swiss Cheese, fine, 12@13c; choice, 11@11½c; fair, 10@10½c.

301 Exchange Place. G. M. LAMB & BRO.

MANCHESTER, ENGLAND, MARKET.

A very firm market prevails at Copenhagen. English prices have risen 3s to 4s. Free on board orders for this week's shipments are very large, so that an absolute scarcity of butter is bound to ensue before shipments are ended. An advance of the official quotation was inevitable. It is now wired four kroner higher. Copenhagen says the advancing movement is likely to continue. Irish Centrifugal Creameries have followed the Danish rise. Several creameries are holding their produce to benefit by the advance. This is a most mistaken policy. No rise in price will compensate for the deterioration of overheld or badly kept butter. The quality and reputation of such creameries must suffer. As much as four kroner over top has been paid for some Danish dairies. The last advance in quotation will help to stop the over-prices. Irish firkin butter and factories share in the rise. It is estimated 250,000 packages are stored in New York in private and public cold stores, or about 20 per cent more than last season. Continued advances in Europe would soon help to bring the surplus American butter to this side. Present quotations for Danish are about 25s higher than at th corresponding period of last year. Trade is however good in Europe and in America and a brisk demand prevails. A change in the weather would probably damp the ardor of speculators, and with a large surplus in America and the part that margarine and process butter can play when prices go too high will act as a modifying influence. 20,941 casks of Danish and Swedish are crossing for next week, being 566 casks increase, and 1,711 casks Finnish, being 205 casks less. Arrivals of margarine via Hull, 10,248 packages, and via Grimsby 5,475 packages.

DOWDALL BROS.

DOESN'T WANT HER NEIGHBORS TO REPEAT HER SEPARATOR MISTAKE.

BALATON, Lyon Co., Minn., July 24, 1899.

(Copy).

THE DE LAVAL SEPARATOR CO.,

Chicago, Ill.

Dear Sirs:—Will you please send your catalogue to Mr. James Hall, Mr. John Murphy and Mr. Brown, all our neighbors, who keep a good many cows and need separators very much. I don't want them so badly sold as I was when I got mine four or five years ago. I was persuaded to take a ——— separator and I regretted it when the first milk went through. If we were able, we would set it aside and get a "Baby," but we cannot do it at present. We hope to find some way to get one in the near future.

Send catalogue to above names at Balaton, and also one to Ernest King, Heron Lake, Jackson Co., Minn., and oblige,

Yours very respectfully,

Mrs. E. A. GLATFELTER.

If any intending separator buyer will take the trouble to send for a De Laval catalogue and briefly study the illustrated differences of system between the "Alpha" disc and other separators, he will not be likely to make such a mistake.

The De Laval Separator Company,

WESTERN OFFICES:	GENERAL OFFICES:	BRANCH OFFICES:
Randolph & Canal Sts.,	74 Cortlandt Street,	1102 Arch Street,
CHICAGO.	NEW YORK.	PHILADELPHIA.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Wanted—Man and wife, no children, for small dairy farm: clean and experienced milkers. State age, wages expected, nationality, and give references. WM. J. HOFSOMMER, Breese, Ill.

Wanted to hire a good substantial and reliable farm hand. Middle aged and single. J. B. SHATTUCK, Cherry Creek, N. Y.

Wanted—A dairyman to take charge of from 30 to 50 cows. Location healthy. Comfortable house. Married man perferred. Address J. H. MINGE, Faunsdale, Ala.

Wanted—At Meramec Highlands, St. Louis County, Missouri, an experienced dairyman milker. Man with a family preferred. Wages $30.00 and house rent. Also wanted, an experienced, well equipped farmer, who might do dairy work during the winter, or man with a family of grown children to combine, both preferred. Address, MERAMEC HIGHLANDS CO., 208 N. Fourth St.. St. Louis, Mo.

A buttermaker that is willing to milk and also a competent man in feeding stock can get a steady situation. Wages to buttermaker $25.00 per month; helper $20.00 per month, year round. Reply and send references to JAMES N. NORGAARD, Wolcott, Col.

Wanted—A good Jersey breeder, feeder and dairyman for small Jersey farm. Must be a good buttermaker. Write stating age, health, competency, experience, references, etc. SPRINGSIDE JERSEY FARM, Denton, Tex.

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada 32-52

Wanted—An expert Northern dairyman, graduate of Wisconsin Agricultural College, and of life-long experience, wants position in charge of southern dairy farm. Will work for salary or on shares, and furnish A No. 1 references. Address E. O. THORSGAARD, Streator, Ill. 26-3

Wanted—A man with family, honest and industrious, to take charge of a 250-acre farm, well improved, with dairy attached, for an interest in profits. A fine opening for the right man. Must come well recommended. Good market for produce. Can sell any quantity of sweet milk at 20c per gal., buttermilk 10c per gal., and butter 25c per pound. For particulars address J. O. THURSTON, Bartlett, Tenn.

Wanted—An able bodied man and wife to work on and have charge of a stock and dairy farm. Address "A. B. C.," General Delivery, Quincy, Ill. 28-2

A Bargain—Ten head of registered Holstein-Friesian cows, butter bred and tuberculin tested. Price, $700.00. For particulars write L. C. MORSE, Sparta, Wis. 28-2

Wanted—A position by an experienced buttermaker. Best of references. Can accept position Oct. 1st. ANTHON STOKKE, Stoughton, Wis.

Auction of Guernsey cattle on Sept. 20th, on farm of GEO. D. TELFER, near Fort Atkinson, Wis. Watch this column for more extended notice. 28-2

For County Fair, Woodstock, Ill.—The North-Western Line will sell excursion tickets at reduced rates, August 28 to September 1, inclusive, limited to include September 2. Apply to agents Chicago & North-Western Railway.

Very Low Rates to National Encampment, G. A. R. Philadelphia, Pa., Sept. 4 to 9, 1899, via the North-Western Line, from all stations, excursion tickets to be sold to Philadelphia, Pa., September 1, 2 and 3, only for trains arriving at Chicago September 1 to 4, inclusive. Apply to agents for full particulars. 28 2

Excursion Tickets to the Great American Exposition, to be held at Omaha, Neb., until October 31, 1899. Via the North-Western Line, will be sold at reduced rates, from certain stations on specified dates. For rates, dates of sale and limits of tickets apply to agents Chicago & North-Western Railway. 22-sp

A Cheese Instructor's Report.

Sample of Work Done by the Wisconsin Dairymen's Association.

GEO. W. BURCHARD, SECRETARY.—Sir:—Inclosed you will please find report of my visit to the ——— factory, along with a duplicate copy of my tests of the milk of that factory.

The original copy has been pasted on the intake door of the factory. I have given all milks at all factories careful and thorough tests all this season, and usually have the results with me at our evening meeting of the patrons, explaining the terms "lactometer reading, and specific gravity" and so on, so that they thoroughly understand just what we are getting at.

I could not possibly get a meeting at the ———factory, as two threshing outfits are at work among the patrons and they could not well come out. I found the ———factory spraying their cheese with formalin to prevent mold, they were not using it every day, and rather slack when they did use it, so were not deriving much benefit from its use.

Mr.——of—— ——factory told me he had been using it extensively in his basement curing room with very gratifying results. He not only sprays his cheese but has jars of the formalin sitting under the curing tables.

I do not approve of it, and do not advocate its use, I very much prefer the burning of sulphur in small quantities or using a solution of borax in the cheese hoop. Still better is an opening in the lower part of the curing room with a ventilator shaft to create circulation, and the generous use of good washing powders with scalding hot water on ceilings and curing tables, or if lathed and plastered, a fresh coat of whitewash.

I am bound for the Popolar factory, of Sauk Co., and from there to South West Wyoming factory, of Southern Iowa Co. This will use up the week as the drives are long, hard ones.

I met Mr. Adolph Schoenman, of Plain, Sauk Co., this evening and he is planning for another big meeting of his patrons next October. He will get out special printed invitations to each of his eighty patrons and and their families, and has booked your humble servant for the address of the evening. I should be pleased to have some member of the Executive Committee, of the Dairymen's Association, present at this meeting if possible, so that he may tell the members at their next annual meeting, something of these evening meetings of the patrons of our Wisconsin cheese factories. I am not quite sure that you can read these lines but I am momentarily expecting the freight east and have written hurriedly. U. S. BAER.

Why Creameries Differ in Prices Paid to Patrons.

ED. HOARD'S DAIRYMAN:—This question is discussed quite carefully by a contemporary, but in the conclusion drawn, one of the main reasons has been overlooked. For a few years I have tried to study this question from various aspects, right on the ground, from actual observation and investigation. My observations were, of course, very limited, and much remains to be done yet before I feel safe in drawing definite conclusions, but under one set of conditions I always found a corresponding result.

Let me illustrate by a few examples. I visited Mr. Jones' creamery and introduced myself by telling him I was not a revenue officer nor a tax collector nor yet a drummer, but simply a dairyman in quest of knowledge.

It was a co-operative creamery and Mr. Jones was manager. He was a very intelligent man and made my stay very pleasant. A wiry little fellow was the butter maker, who had intelligence enough to command $75 per month, while strapping big fellows were offering their services for $40. I met the board of directors and what do you think, they really had a few books on co-operation and also some bulletins on the same subject. They were intelligent, up to date people.

I met most of the patrons who were, with few exceptions, quite intelligent, all readers of some up-to-date dairy or agricultural paper, and knew how to produce good milk and deliver it to the creamery in a good condition. Those were a few of the conditions, and what were the results? Butter was then quoted in Philadelphia at twenty-four cents.

The patrons were paid twenty-three cents per pound of butter fat, besides I was told that unless extra expenses were incurred quite a handsome quarterly dividend was made. The butter was of such a quality that there was a demand for it, nearly all of it was contracted for at an advance.

As nearly as I could learn, and I could come very close, as everyone was ready to cheerfully give information, the patrons realized from butter alone on an average $51.00 per cow per year. After completing my memorandum and notes of this enjoyable visit, I wrote below: "This creamery is a financial and moral success, and the whole secret of the success is intelligence, *intelligence*, INTELLIGENCE. The people who produce the milk are intelligent, so are the manufactures the sellers and the buyers of the butter." Not fifty miles away I visited Mr. Smith's creamery. Mr. Smith was the owner, the manager and the butter maker. He did not know good butter from bad and was so suspicious that I had much difficulty ascertaining any facts I desired, still I learned first that he was a "conceited ignoramus" and asserted that he knew all about the business.

He was paying sixty-five cents per one hundred pounds for milk. He was getting (quotations were same as before) twenty-one cents for his butter. This I only learned through his "cussing" the commission merchants. He said they were a set of swindlers and never paid what they quoted. The patrons were of the same stripe, ignorant, suspicious and selfish.

Did they read a dairy paper? No, some of them read the "Snideville Snider" and that cost a dollar and they could not afford to spend more money on papers, With the greatest difficulty I learned the number of cows and got the figures from milk sheets, all daubed and greased up to make them quite illegible. But after I had patiently listened to the patrons denouncing the creamery owner as a fraud, and the creamery owner denouncing everybody but himself as a cheat, I came close enough to actual figures to be sure that the patrons of Smith's creamery realized on the average not more than $24 per cow per year and possibly a little less. Everybody said it don't pay and if they told the truth in anything I felt sure this was only too true.

Poor, ignorant, superstitious owners of poor cows bringing a poor quality of milk to an ignorant creamery manager, who makes a stuff that must be sold at a sacrifice to poor, ignorant buyers. At the bottom of the notes on this creamery appear three words in large letters. Failure from ignorance.

L. W. LIGHTY.

Patrons' Bulletin.

The following is the report referred to in Mr. Baer's article, on this page:

Factory. AUGUST 15, 1899. Factory.

BABCOCK MILK TEST.				WISCONSIN CURD TEST.		
No. of Sample.	Butter Fat Test.	Lactometer Reading, Specific Gravity.	Yield of Green Cheese per 100 Pounds of Milk.	Flavor.	Texture.	Remarks.
1	3.50	1.0304	9.35	Good.	Good.	Clean, solid-bodied curd.
2	3.20	1.0304	8.89	Good.	Good.	Close, meaty curd.
3	3.00	1.03	8.71	Fair.	Soft, mushy	Few pin holes, old musty flavor.
4	3.80	1.0314	9.94	Fair.	Fair.	Close body, weedy flavor.
5	3.80	1.032	10.08	Bad.	Poor.	Barnyard taint, full of gas.
6	3.50	1.0278	9.09	Fine.	Fine.	Splendid good curd.
7	3.40	1.0309	9.32	Good.	Good.	Good, firm body.
8	3.60	1.0309	9.63	Fair.	Fair.	Mushy, sticky textured.
9	3.40	1.031	9.33	Fair.	Fair.	Close body, but too soft and pasty.
10	3.20	1.0286	8.62	Fine.	Fine.	Nice, clean, firm body.
11	3.60	1.0298	9.60	Fair.	Good.	Slightly tainted with weeds.
12	3.90	1.0305	9.97	Bad.	Poor.	Very gassy, spongy, strong bitter flavor.
13	3.70	1.0297	9.52	Bad.	Spongy.	Very gassy, very badly tainted.
14	....	.....	....	.....	.....	Did not haul on this day.
15	3.50	1.0312	9.48	Fair.	Fair.	Showing some small gas holes.
16	3.70	1.031	9.78	Fine.	Fine.	Good textured curd.
17	3.60	1.032	9.77	Bad.	Bad.	Very gassy, floating, spongy curd.
18	4.00	1.032	10.39	Fine.	Fancy.	A perfect curd in every way.

NOTICE:—Nos. 5, 12, 13 and 17 milks will not yield the cheese credited to them above, because of the bad flavors and gassy fermentations which they contain. Where cheese is made from such milk the cheese maker is compelled to develop the maximum amount of acid, cook to the limit and resort to extreme measures in the process of manufacture, all at the expense of quantity as well as quality.

READ THIS!—Acid dissolves curd, causing a loss of solids; therefore 100 pounds of bad milk will not only ruin the flavor of a vat of 5,000 pounds of good milk, but will also make less cheese per 100 pounds of milk. That cheese maker does not exist, and never has existed, that can produce a first-class cheese from gassy milk, or milk containing bad flavors.

IMPORTANT!—As cheese is an article produced for human consumption, it is the duty of every milk producer to exercise every precaution to keep his milk and all milking utensils in a neat, clean condition, and to furnish nothing but good, clean, pure milk to the factory. It is a duty you owe all mankind, as well as your fellow patrons, especially do you owe it to the hosts of little ones who are likened unto the Kingdom of Heaven. U. S. BAER.

State Cheese Instructor for the Wis. State Dairymen's Association, Fort Atkinson, Wis.

"Boiled Butter."

The tendency of the age seems to be to find substitutes for almost everything. The object with these substitutes, on the part of the manufacturer, is of course to have the imitation resemble the genuine so closely that it cannot be distinguished by the average consumer; then to set a price upon it just enough below the article that he copies to insure its ready sale. Of course it is not true in all cases that fraud is intentionally perpetrated, but it is so in many, and especially so perhaps in the imitations of pure foods. In dairy products there is nothing imitated more than pure butter. As its substitutes we have oleomargarine, butterine, peanut butter, cocoanut butter and "renovated" butter. This last product is known by a good many names—"boiled butter," "aerated butter" and "process butter."

This product is a comparatively new competitor of creamery butter and it is made in the following manner: Old, country butter of various degrees of rancidness and color, that is, so rank in taste, smell and appearance as to be unsalable for direct consumption, is thrown into a tank surrounded with water at a temperature of 100° Fahrenheit or over, and melted. When the mass has become thoroughly melted the vat is skimmed, leaving the butter fat at the bottom. It is now removed to another vat similar in construction to the first, where, as the mass at this stage of the process has a very bad odor, the next step is to remove this disagreeable and disgusting smell. This is done by pumping the fat up in a pipe, by means of a rotary pump, and discharging it into the vat again through a strainer, which allows it to fall in small streams. The exposure of the fat to the air for some time removes the odor. After the fat has been sufficienly aerated in this manner it is ready for the next step. This is the adding of about one-fourth as much skim milk as there is fat. A perfect emulsion of the fat and skim milk is made by the same pumping operation, except that the strainer is removed. The emulsion is then run in a vat of ice water where it is quickly chilled, taking the granular form and looking like butter before it is salted and worked. It is now salted, worked, and printed, or packed in tubs ready for the market.

Owing to the large amount of moisture in it, process butter contains only about 75% of butter fat, while butter contains from 83% to 88% of butter fat. As it is mixed with so much skim milk, it also contains a relatively large amount of casein, which causes it, unless kept at low temperatures, to lose its flavor very soon.

While it is fresh it is not readily detected as process butter, and is sold in direct competition with pure creamery butter. As it will not keep well, becoming entirely unfit for consumption if held for any length of time under ordinary conditions, it is a menace to the manufacture of pure butter.—H. HAYWARD, in *National Stockman*.

Charlock Spraying.

Judging from newspaper reports, the results of spraying charlock appear to have been very varied. As our experiments have now proved, beyond doubt, to be a complete success, it may be well to describe how and when the operations were carried out. The field experimented on has been a great grower of charlock for many years, and in this respect is considered the worst in the neighborhood. It is about two acres in extent, and was seeded with oats after lea. Before spraying, the charlock was in full bloom, standing from twelve to fourteen inches high, about on a level with the oats. The leaves of the charlock had become small and the stems rather tough. It was feared, at the time, that we were a little late in starting the spraying, which afterwards proved not to be the case.

The first plot of nearly three-quarters of an acre was sprayed on Monday, June 12, with 2% solution of copper sulphate, at the rate of forty gallons per acre. The weather was hot and dry, and had been for some time. The plot was examined next day, when the charlock had the appearance of only being slightly checked. It was then decided to spray a small plot with a 2½% solution, at the rate of sixty gallons per acre. This was done on Wednesday, June 14, and on the same day another plot of about half an acre was sprayed with an 8% solution of sulphate of iron at the rate of sixty to seventy gallons per acre. The field was inspected on Friday, June 16.

Plot 1 (sprayed with 2% solution copper sulphate). A large proportion of the charlock was dying off; corn slightly affected by the spraying.

Plot 2 (sprayed with 2½% solution copper sulphate, sixty gallons per acre). Charlock almost entirely destroyed. Corn affected by the spraying.

Plot 3 (sprayed with 8% solution of iron sulphate, sixty to seventy gallons per acre). Charlock turned black and appeared to be entirely destroyed. Corn only very slightly affected by the spraying.

In order to make comparisons and draw conclusions, one part of the field was left unsprayed. The line of demarkation between the sprayed and unsprayed was as definite as between the plowed and unplowed portion of a lea field. A few days after the spraying some heavy showers fell. This was just what was required to see if there was sufficient nourishment left in the stem to produce seed. On examining the field at this date, we find several plants producing pods on plot No. 1, but about 75% of the charlock has been killed. On plot No 2 about 97% has been destroyed. Although the corn received a slight check after spraying, it appears to be a full crop now. On plot No. 3 fully 95% of the charlock has succumbed to the spraying. The corn is slightly darker, and appears to be a fuller crop than the unsprayed adjoining. The chief conclusions that may be drawn from the experiment are as follows:

1. A 2% solution of copper sulphate, or an 8% solution of iron sulphate is strong enough.

2. It is better to increase the number of gallons of solution per acre than to increase the strength of the solution.

3. Although forty gallons of solution per acre is sufficient when charlock is not abundant, at least seventy gallons per acre should be used when charlock is thick.

4. Each plant must be thoroughly drenched in order to prevent it producing pods.—HENRY F. HILL in, *Farmers' Gazette*, Ireland.

Concerning Tuberculosis.

ED. HOARD'S DAIRYMAN;—Please accept my thanks for so courteously explaining your views upon what I inadvertantly called the "spirit" of the article on page 460. I must say I am in sympathy with what you say, and am simply trying to get the opinions of various authorities upon the necessity of the tuberculin test for tuberculosis in cows. It isn't a subject on which I am entitled to write with any degree of authority from researches of my own, and only say what others, who are more or less competent to speak, have said. It has been my good fortune as manager of this business to have talked with hundreds of physicians in this and other cities in the Eastern states, as well as to have attended various meetings of hospital staffs, and thus have been afforded opportunities for personal discussion on this and other subjects. Some have flatly re-

fused to believe that there was much possibility of a healthy tissue in a human being becoming infected with tuberculosis germs in milk, or even that such germs were liable to be there, while others, and really the larger number, have the opinion to the contrary.

As a matter of fact we do, as a precaution, have all our cows tuberculin tested when deemed necessary by the veterinary who has charge of our herd. Cleanliness in barns, cans, milkers, utensils, in fact evrything, is rigidly enforced, as we believe that cattle furnished an abundance of pure air, light, pure water, proper food, and kept *clean* in *clean barns*, are the only ones not liable to disease constantly, and fit to furnish milk for the hundreds of babies and children dependent upon it.

Yes, certainly, most certainly, "there is danger in traveling in boats, in carts or wagons, or even in journeying afoot," and *yet* people *do not* ordinarily use these conveyances when marked "condemned" or "unsafe," and I question if you would be willing to regularly use milk from a cow which had tuberculosis.

I surely am not an "alarmist" on this subject, though I do believe that every possible precaution should be used in producing milk for family use, and, using your figure, while one hundred men might safely ride in a condemned boat, wagon or cart, the one hundred and first man would lose his life, and who is to blame but the man allowing such boat, etc., to be used? I truly fail to see the wisdom of trying to escape looking squarely at a danger and remedying it, because we surely do consider there is danger here, however much we may try to avoid looking at it, and to keep ourselves from acknowledging it. WALTER HASTINGS.

Providence, R. I.

Good Pork for Three Cents a Pound.

There is *pork and pork*. Pork that is made in filthy, ill-smelling pens, fed on city swill, offal from slaughter-houses, dead horses, and other foods of like character, and finished off on corn-meal, which is fit only to breed scrofula and other maladies that afflict humanity.

Pork made in pure air, open fields, clean pens, fed on grass or other cooling and succulent foods is healthy, sweet, delicious and fit to be placed on the tables of the most fastidious epicure of any country.

Experiments made at stations have demonstrated beyond question that the character of the meat produced is very much due to the nature of food eaten, and in no animal more so than in the pig.

That corn foods of like composition produce meat largely fat with small bones, and but little muscle or lean meat, and that dry and hard; while nitrogenous and succulent foods make strong bones, plenty of blood and lean meat, and that juicy and tender.

They have further shown that this modification or change of character can only be made when the pig is young and growing. As in the human family, "early impressions are most lasting and hard to obliterate," so in the pig, it is hard to overcome, the effect of the food in the first few months of its life.

What the farmer wants to know is, how to make pork most healthful and of highest quality, and consequently be most in demand and bring the highest price. Luckily, such pork can be produced at the lowest cost. In order to make such pork cheap he must start right. Of course there is much in breeding, but so long as there is so much more in feed and care I am not going to enter into a discussion of breeds further than to say select one that will respond quickly to good feed and care.

When such an one is found, remember there are certain principles in animal nutrition that must be understood and certain conditions complied with to produce the best pork, at least price. Among these principles the following are important:

The pig eats, first to sustain life, after that to increase in size.

The most of the food used in sustaining life goes to support bodily heat.

The balance in replacing worn-out tissues and keeping up the functions of life.

All growth comes from food eaten in excess of that necessary to sustain life.

The elements of nutrition needed in the food vary according to the functions to which they are to go. Those used to keep the pig warm must be carbonaceous or heat-producing.

The supply of fat in the growth or in fatting comes from the same element, which is also largely drawn upon by the exercise the pig takes.

The hair, hoofs, lean meat or muscle as well as the blood comes from the nitrogeneous elements, while the bones are from the mineral elements in the food.

If the pig be fed wholly on food deficient in any of these elements it cannot thrive. If lacking in bone material its frame will be dwarfed and its bones weak and liable to break. If on food rich in the carbonaceous and lacking in the nitrogenous elements it will cease to grow and become excessively fat. It may be even "starved to death as fat as butter."

If on the contrary, the food contain an excess of the nitrogenous and bone-making material the pig will develop a larger frame with lots of muscle and very little fat.

Another very important principle is involved. The digestive and assimilative ability of the pig is very much greater than when it comes to "hog-hood."

And lastly, but by no means least, comes the fact that a pig once stunted *can never after* be made to make pork at a maximum profit.

With these principles established as well as the fact that people now call for, and eat lean meat, and reject that which is unduly fat, it follows that to make the best pork at lowest cost the pig must be well-bred, started right and then fed, from its natal day till it brings up on the block, on the right kind of food to produce juicy, lean meat and enough to make the largest gain.

The pig that is wintered weighing no more in the spring than in the fall has been fed all winter at a dead loss, and worse still it has become stunted and dwarfed beyond hope of recovery or profit from subsequent feeding.

The best pork, most economically made, is that which is produced on the pig in the shortest time after it is born, one that gets most of its living on a fresh pasture in the open summer field.

But in order to get the pigs in the spring for this purpose we must winter a lot of breeding sows to drop pigs ready to go on to the fresh pasture of early spring. To do this successfully and cheaply is one of the prime factors in this whole problem.

An unhealthy sow cannot produce a healthy, thriving pig. An over-fat sow will be sure to bring small little pigs hardly worth the raising.

What is wanted is a strong, healthy big-formed pig with lots of growth and to get such an one we must have a strong well developed muscular sow in the most robust health, with a system so nourished as to be free from all feverish tendency, and natural in all functions and able to furnish an abundance of good milk for the pig from the moment of birth.

Such a sow in such a condition can never be had by feeding on any food rich in carbonaceous material and running out of doors and sleeping in a snow bank.

She must be put into a dry, airy, well-ventilated, warm and roomy pen and fed on cheap, succulent food, nitrogeneous in its nature and with an abundance of bone-making material. A dozen sows weighing from 200 to 300 pounds each may be put into a pen as above described, 30x40 feet, with good height to the ceiling, and be safely wintered on six bushels of mangels and 24 pounds of coarse middlings or fine, re-ground bran, each day, with all the good early cut, well cured clover hay they will eat, and be in the finest condition to farrow an average of eight well-developed, healthy pigs each. The mangels should be fed whole so as to give the needed exercise in eating them,

These sows should be bred so as to farrow in March or very first days of April, and, of course, a few days before each is expected to farrow, she should be penned off by herself, with the proper conditions of bedding, etc., to render it sure she will have no difficulty in bringing forth the expected litter. As the mangels can be grown very cheaply, and the bran bought for from $10 to $15 per ton, the cost of wintering will be but very little, and your pigs cost only a song. Having thus secured a lot of pigs very cheaply, and what is of more importance, having them well born, the remaining thing to do is to feed them at least cost on the most desirable food. No food is better or cheaper for the young pig, than sweet skim milk when it can be had. But as soon as old enough, pigs should always have the use of a pasture field. Clover makes an excellent pasture for pigs, but no plant is better food for the pig or more easily provided, than Dwarf Essex rape; by having land rich and prepared in the fall, it can be seeded to rape with the first warm days of spring, and in from four to six weeks be large enough to begin feeding. Pigs are very fond of this, and may be pastured on it, or it may be cut and fed to them in another place. If the rape gets the start of pigs, it should be mowed off for sheep or cattle, in any case it grows quickly after being cut or eaten off, so that a comparatively small field will feed a lot of pigs.

In addition to all the rape or clover they will eat, the pigs should have some dry food; for this purpose nothing is better than coarse middlings. Bran, even if ground very fine, is not as good for the young pig; it is all right for feeding the old sows in winter, but is too coarse and laxative for the pig. Unless it prove too laxative, the addition of a little linseed meal, one part to four of middlings will be a good change for the pigs occasionally.

They should have all the middlings they will eat clean so as to keep them gaining as fast as possible until they weigh from one hundred to one hundred and twenty, live weight. There may now be added to the feed one-four h its weight of corn meal, and this should be increased from time to time until the food is half corn meal.

As soon as the pig will dress from one hundred and fifteen to one hundred and seventy-five it should be sold, and if one is reared and fed as above indicated it will have cost less than three cents a pound for the dressed weight and the meat will be lean, tender, juicy and sell for such a price as to leave what should be a very satisfactory margin of profit.

If the following mixture be prepared and kept in a bag under cover and always accessible to the pigs and hogs, it will be found very beneficial and go far in keeping them free from internal parasites:

One and one-half bushels corn cob charcoal, three pecks hardwood unleached ashes, fifty pounds fine bone meal, six pounds salt and one pound copperas.

Break the coal quite fine, mix coal ashes and bone meal together, and dissolve salt and copperas in water, and with the solution sprinkle the mass frequently, stirring so as to have all well incorporated together. To prepare the cob coal, dig a hole in the ground, start a fire in the bottom, pile on the cobs, and cover quickly. Leave just vent enough so the whole mass will get on fire, and then cover up and leave until the whole is cooled down. This is a capital condiment for the hogs at all times.—J. S. WOODWARD, in *Farming*.

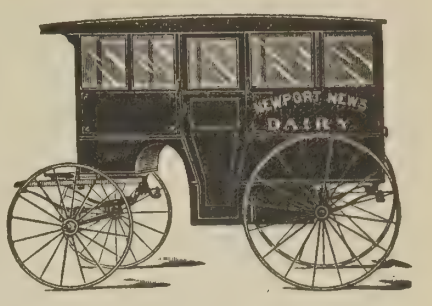
Dairy Legislation in North Dakota.

The Dairy and Food Commissioner of North Dakota is sending out the following letter, calling attention to the recently enacted laws on dairy products.

We notice that boiled butter is slowly taking its place beside oleo. The letter is sent to all dealers, handlers and producers of dairy products:

Your attention is respectfully invited to the accompanying law recently enacted, governing the sale of oleomargarine and butterine, and also to what has been commonly known as "boiled or process butter;" also to those sections relating to the procuring of licenses by owners of milk dairies and dealers in milk, living in cities of over one thousand inhabitants, and that every creamery and cheese factory shall procure a stencil or brand bearing a suitable device, or words which shall clearly designate the quality of the product manufactured, as well as the number and location of the factory; also that said factory shall, on the 1st day of November each year, make a full and accurate report to this office, of the amount of business done during the year.

Demand for Dairy Machinery in Belgium.



ED. HOARD'S DAIRYMAN:—Consul Le Bert writes from Ghent, May 19, 1899:

I have this day received from Mr. A. Heynssens, Rue Haut Port 12-14, a letter asking the names and addresses of important firms in the United States manufacturing dairy machinery, such as churns, separators, butter workers, dairy articles, refrigerators, cheese making machines, etc. He desires firms not as yet represented in Belgium and asks that catalogues and circulars, with conditions of sale, be addressed directly to his firm. This house is one of the oldest and largest in the provinces of East and West Flanders, handling the line of goods mentioned. Upon inquiry, I learn that none of these articles are manufactured in Belgium.

The importations to both Flanders are chiefly from England and Denmark. Considering the vast dairy industry of the Flanders and our improved apparatus, there should be, with proper representation, a wide field for our manufacturers of dairy machinery and utensils. HENRY E. ALVORD.

Chief Dairy Division, Washington, D. C.

The World Cannot Show Its Equal

In STYLE, CONVENIENCE and DURABILITY.

Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairyman at bed rock prices. For description and price address,

THE NATIONAL WAGON CO.,
Chillicothe, Ohio.

BALE YOUR HAY

It will keep better, sell better and save room. Rats and mice can't cut and destroy baled hay. The best and most rapid machine for baling purposes is

Steam and horse power.

The "ELI" BALING PRESS.

Made in 38 styles and sizes to suit every case. All steel, light, strong, lasting. Write for free illustrated catalogue.
COLLINS PLOW CO., 1155 Hampshire St., QUINCY, ILL.

There's No Waste

either in knocked off ears or from sour, musty and mouldy corn fodder when using this

SCIENTIFIC CORN..... HARVESTER

Being strong and well made of good material it will last. Every farmer can afford one. Send for catalogue, I.
THE FOOS MFG. CO., Springfield, Ohio.

Farm for Sale. 163 Acres—1½ miles from prosperous County seat, with population of 4000. Good four roomed house—large roomy barns and other out buildings. 2000 bearing Peach trees; 1000 young Peach trees—500 thrifty Apple, Pear, Plum, Cherry and Quince trees—good fences and plenty of water. Now stocked with **Registered Jersey Cattle.** For price, terms, etc., address,

MAPLE GROVE FARM,
Hocking County. Logan, Ohio.

Farms For Sale.

$15 to $40 an Acre will buy the very choicest farm land in St Croix County. It is the best black loam and clay soil and well watered. Farms from 40 acres to 800 acres to suit purchasers; German, American, Scandinavian and other settlements. Come or write,

W. E. WEBSTER, Hudson, Wisconsin.

GOLDOMETOR for locating gold, silver and other minerals. In a pocket case. Also Rods and Spanish Needles. Catalogue, 2 cent stamp. B. G. STAUFFER, Dept. H. D., Harrisburg, Pa.

Blackleg, Its Nature, Cause and Prevention.

[Paper read before the Utah State Farmers' Institute by PROF. L. A. MERRILL.]

There is possibly not a section of country in the United States so little affected by contagious diseases as is Utah. As an explanation of this fact, we find in the high altitude, the dry climate and abundance of sunshine; conditions unfavorable to the growth, development and perpetuation of infectious diseases.

Most of the diseases of the human family,—and this is also true of our farm animals—are due to microscopic organisms, principally vegetable, which pervade the animal tissues, and the symptoms of disease are manifest because of their presence. When we understand that these organisms are so minute that 1,000,000 of them may be found in a single drop of water, then we can realize why, for hundreds of years, before the introduction of the microscope, the origin and contagious character of these diseases were sources of doubt and mystery.

There are certain kinds of substances in which these bacteria thrive better than others, just as there are certain kinds of soil in which certain kinds of cereal crops thrive best. For example, the blood of our domestic animals furnishes an excellent home for germ life, and in consequence there are many diseases of farm animals due wholly to the presence of these germs.

BLACKLEG (SYMPTOMATIC ANTHRAX).

This is a specific infectious disease probably not communicable at all by a volatile poison. It is a disease especially of cattle, but may be communicated to all species of animals. It is especially a blood disease, due to a rod-like bacteria (Bacillus Anthrax).

It is not a contagious disease, that is, an animal will not contract it by simply coming in contact with another. As a rule, the germ is introduced into the system through some wound or abrasion of the skin or by means of food or drink. The blackleg bacilli are not able to multiply in the presence of oxygen; in technical language it is anaerobic.

This explains the fact, that while they do not develop on parts of the body exposed to free air, such as the skin and mucous membranes, the germs find the conditions necessary to their growth in the parts underneath the skin, as the underlying connective tissues to which the air does not have access. One characteristic point to be noticed in connection with this bacillus is, that one of the ends of this bacillus or germ is enlarged. This enlargement consists of a hard shell-like substance, which protects the spore stage of the bacilli. A structure of this kind would naturally be resistant to external influences, being able to withstand heat, cold, light, and other unfavorable conditions, and even decomposition in a dead body, which would more quickly result in the destruction of unprotected bacilli. With such a protection the blackleg germ may exist for a long time outside of the animal body, and it is very difficult to eradicate the disease from a pasture which has once become infected.

The germ possesses a high degree of vitality, in out door conditions. It is endowed with practical perpetuity. Dr. Stalker, of Iowa, relates an incident in which a calf died from blackleg. Seventeen years after the grass from over the grave of this animal communicated the disease.

SYMPTOMS.

The first thing that you will notice is that the animal appears dull, stupid, and remains apart from the rest of the herd. Examine with a clinical thermometer, and you will find an intense fever—104-106° F.

The pulsations are so rapid that they can hardly be counted, respiration becomes accelerated, the animal moves around with difficulty, frequently lies down, and when water is near at hand drinks at short intervals and but little at a time; the mucous membranes are at first dark red and congested, but they change in the course of twelve hours to a dirty leaden or purplish color. The most important diagnostic feature, is the development of a swelling or tumor under the skin; it is usually noticed on the thigh or shoulder, and it is to the effects that this swelling produces that this swelling gets its name "blackleg" or "black quarter." By moving the hand over the parts affected, one can hear a crepitating sound, and percussion gives a clear resonant tone, due to the collection of gas in the affected parts.

If an incision be made into the swollen parts a frothy dark-red fluid is discharged. If the incision is made while the animal is alive or soon after death, there is no offensive odor to the dischage, but decomposition takes place very soon after death.

The symptoms become more and more intense until the temperature may exceed 140 per minute, the animal is unable to rise, the extremities become cold, and just before death, the temperature falls below normal. There is trembling of the muscles, which as death approaches, may develop into violent convulsions.

AGES OF CATTLE AFFECTED.

It is more likely to affect young animals than old ones. It attacks cattle usually between the ages of six months and two years, but it may attack cattle either over or under these ages. It is not uncommon to see the disease at any period of the year in this state, though very few cases are seen during the summer months. Farmers usually complain that it is the best bred and most thrifty cattle in the herd that are affected. This is true because the blood of a well-conditioned calf furnishes a better soil for the organism, being charged with plastic fatty material, conditions favorable to the rapid development of the blackleg germ.

TREATMENT.

Owing to the rapid and violent course of the disease, treatment is of little or no avail. Numerous remedies are in use, but the cases of recovery on record are exceedingly rare. Incisions are sometimes made into the affected parts, and some strong disinfectant is used, as carbolic acid, corrosive sublimate, creoline, solution of salts (iron and copper). Sometimes the parts affected are cauterized with the hot iron, but this seems to me to be a prescription for the effects produced without first removing the cause. Bleeding from the jugluar vein in early stages is also practiced, from one to four quarts of blood being drawn from the animal. Stockmen who have had considerable experience with blackleg, think that exercising the animal violently, when the first symptoms are observed, gives good results. A man with a horse runs the sick animal about as long as it can go without suffering. After the violent exercise, the animal should be kept moving gently until it is cooled off. The explanation of this treatment is that the violent exercise keeps the blood from settling in any part of the body. That class of remedies known to be destructive to germ life, as indicated in this disease, tincture of iron or one per cent solution of carbolic acid, is sometimes injected hypodermically in the affected parts, and this has been attended with good results.

DISPOSITION OF BLACKLEG CARCASSES.

If, after the calf dies, the calf should be used for pig feed, you will get another manifestation of the same disease in the hog. Here it will be known as "black tongue", and is characterized by a gangrenous condition. If the carcass is left unburied, the germ may come in contact with other calves, and thus spread the disease. Vermin or birds also scatter the infection. It is always advisable, therefore, to burn the carcass immediately, and if possible, right at the point where the animal died. If the animal is buried, it should be placed in the ground at least six feet, and the carcass well covered with lime before the earth is thrown on. The ground should also be covered with lime or some other active disinfectant.

PREVENTION.

Improvements made in the condition of the soil may contribute in great part to the disappearance of anthrax. It is proper, from the blackleg standpoint, to drain swampy grounds and favor the exit of the water, also to prevent animals from feeding upon infected pastures. It has been known for a long time that most animals, which recover from blackleg, possess a more or less complete immunity. It has also been observed that occasionally individual calves have a natural immunity. These facts have given rise to researches which have led to the discovery of means enabling us to create immunity artificially. Pasteur in France, discovered that this germ could be cultivated under various conditions; that he could even devitalize the germ, inoculate it into an animal, give the animal a mild form of the disease, and thus render the animal immune. The scientific researches of Pasteur have been turned to a practical application which has resulted in the saving of thousands of dollars in the United States.

To-day the best preventive treatment for blackleg is vaccination of susceptible animals with a weakened virus. This virus is prepared as follows: The "bruised-looking flesh" from an animal that has died from blackleg is cut from the affected quarter, cut into small bits, dried into a temperature of near 100° F., pulverized and the coarser particles taken out. The powder is then heated for six or seven hours at a temperature of about 180° to 200° F. The vaccine is sent out by the bureau of animal industry at Washington, D. C., in packages of ten and twenty-five doses per package. This powder is dissolved in water and is then

ALBION JERSEY HERD is headed by

Very handsome . . . Send For Pedigree. **$50.** **J. P. BRADBURY Pomeroy, Ohio.**

ready for use, but must be used within twenty-four hours, after being dissolved in water. This vaccine is introduced under the skin of an animal by means of a hypodermic syringe. The most convenient place to inoculate is on the side of the neck, just in front of the shoulder, where the skin is loose and rather thin. This system of preventing blackleg has been carried on quite extensively in some of the eastern states, and appears to have given excellent results. It is to be hoped that in this state stockmen who are interested in this disease may investigate the method of vaccination, adopt it, and thus effect a saving of thousands of dollars annually.

Filling Silos, Covering, etc.

Fast or slow filling is debated, but the only difference amounts to about this: With slow filling there is more time allowed for the material to settle, and one gets more material into the pits if he is a week about it, than in two days. In Ohio we use the rapid filling. Where one fills two silos, and can do so, it is a good plan to fill into one a half day, and then the other. The carrier of our machine carries over one silo, and throws into No. 2; so by simply removing a trap slide in the carrier over No. 1, or replacing it, the silos can be alternated in filling, without changing the machines. We know of no tests that place greater feeding value upon slow, rather than a fast filled silage. In a fast filled silo, there is a greater show of space after it has settled. To overcome this loss of storage, some silos are provided with a top rack some eight feet high, about the top of the silo, and this rack is filled, and as the silage below it settles, it finds its place in a few days in the pit, which, when settled, will be brimming full.

How shall the silo be covered to protect it from the air? Does it need any cover at all, more than the roof above it? Some silos now are even denied this protection. Certain it is, that no one now covers silage with plank, paper and weights. The most simple cover, and extensively used, is no cover at all, simply putting the litter about the cutter, upon top of the silage, making it firm by treading and leaving it, allowing the top layer of a few inches—three or four, possibly six—to mold and rot, and seal itself away from the air. A few (the third or fourth day after filling, and some treading) sprinkle twenty pails of water on the surface of the silage, and thus hasten the molding and sealing. As good a plan as we knew of, is to copy the last method, and add it to a bushel of oats, raked into this warm, wet surface, and grow a cover of oat roots mixed with the decayed silage. The growth will soon fall down and die, making a cover we have never seen excelled, and so matted that it is easily taken off. Others put on wet, old straw, and some use saw dust wet down, and others commence at once to feed from the silo as soon as filled, and, hence, need no cover.

In the winter, on approach of very cold weather, it is a good plan to put some boards over the silo, and cover with a half ton of straw. This holds in the heat, keeps out cold air, and more germs find in the warm silage a pretty good home to colonize in, and then in cold weather the cows get a warm breakfast, instead of now and then an iced menu.

The reports from all sections of the country this year, 1899, give to the silo greater prominence than ever, in the economy of cattle feeding. In no year of its history have the inquiries about it been so numerous, and so much along the lines of definite inquiry. Criticism is rarely heard. To profit by their use seems to be the one desire. We know now of no market objections to the milk of silage-fed cows—good silage. The fancy milk for Philadelphia, New York and Boston, is three-fourths of it, silage made.—John Gould, in *Ohio Farmer*.

The annual report of Osage Co-operative Creamery Company, of Osage, Ia., states that the company is operating on the gathered cream plan, that farm separators are being very largely used by the patrons, with the result that the cost to the farmers of hauling their butter, producing and manufacturing it, is extremely low; a very great difference between what it costs in the sections where the amount of milk is not large and the hauling expensive.

Clover Failure.

As a rule, not more than one clover field out of every three or four is a good stand, even in a favorable season, and usually it is the fault of the way the field is managed, either at sowing time or after the nurse crop has been taken off. Most farmers do not cover the seed deep enough. One of my neighbors has been trying to seed a certain piece of ground for four years and has always failed. He invariably sows his nurse crop (usually oats), then waits three or four weeks and then sows his clover seed on the hard ground without any covering. The result is, the seed does not come up, or if it does come up and live until harvest it is sure to die when the grain is removed and the young plants are exposed to the hot sun. The root is not deep enough to stand the dry weather that is almost sure to occur about harvest time and directly after harvest.

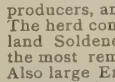
Fall wheat or rye is the best nurse crop I have ever tried, preferably rye, but in many parts of the country oats is the principal small grain crop and must be depended upon for a nurse crop. In seeding clover with oats I cultivate my oats in and harrow once to smooth the surface of the ground somewhat in order that none of the seed will get covered too deep. Then I sow my clover seed at the rate of ten pounds of clover and five pounds of timothy seed per acre. I harrow enough after sowing the seed to thoroughly pulverize all clods and smooth the surface. Do not be afraid of losing the seed by covering it up; it will come out all right.

If you use fall wheat or rye, sow your grass seed as early in the spring as you can harrow the field and harrow until the seed is well covered; it ought to be covered not less than one inch deep, and two is better if the land is at all light. I sowed a field of rye to clover in the spring of 1897. The ground was quite hard, so I harrowed it two or three times before sowing the seed in order to get a good seed bed, then I sowed the clover seed and harrowed as many times more. My neighbor told me I had ruined my rye, but I thought not, and at any rate I cared more for a good stand of clover than for a few bushels of rye. The result was I had a fair crop of rye and a splendid stand of clover. The rye being somewhat thin gave the clover a chance to do its best.

Many times the nurse crop is left standing until it is too ripe. Let the nurse crop be what it may, it should be cut as soon as possible, for every day it stands after it could be cut lessens the chance to save the young clover plants, for it rapidly absorbs what little moisture there is in the ground and thereby robs the clover.

If the conditions are favorable after harvest, and nothing is done to prevent, the clover will head out. It is not advisable to let it head, for it is the nature of clover, after maturing a crop of seed, to die. If the field is so situated that you can pasture the clover off, it will be all right, but if not convenient to pasture, run the mower over it set high enough to clip the heads nicely and let them lie on the ground. In cutting the nurse crop cut the stubble as high as you can, as the stubble will help to catch the snow and protect the young clover. Do not pasture off too short.—*Prairie Farmer*.

Moulting and Laying.



The moulting of hens is usually from June to November, sometimes extending well into the winter. The moulting period is not the same with all hens, nor does a single hen begin at the same period every year, but usually a month sooner or later. For instance, a hen beginning to moult in June may not begin the next year until July, and such hens will moult later every year, until their moulting period reaches into the winter. The hens that begin to moult early are those that finish their moulting, and are ready for laying before winter commences. Having then completed their growth of feathers, they are in excellent condition for doing service, but should the process of moulting extend into the cold season, the hens that have not finished will probably not lay until spring, consequently, the matter of moulting is one which all who are interested in fowls must consider. The moulting process requires three months, and as the production of feathers demands a large proportion of nitrogen and mineral elements, it becomes necessary to supply the fowls with something more than grain and grass.

Carbonaceous food exclusively is detrimental, as the hen is rather inconvenienced by the fat stored on the body, rather than benefited thereby, and yet the majority of poultrymen feed liberally of grain to their moulting hens in the belief that such food is the best that can be given. The food should consist principally, of ground meat or cut green bone, that has a fair proportion of adhering meat, but all fat foods should be avoided. A bran mash composed of bran and cooked potatoes, will provide an agreeable change, while ground bone, milk and a little sulphur in the food once a day will be beneficial. All hens not yet having commenced to moult will prove poor layers before Christmas, and if such hens are fat they should be disposed of. It is a well known fact, that has been repeated in these columns frequently, that if a hen or pullet does not begin to lay before cold weather, she will perhaps, not begin before early spring, but if she starts in to lay before winter begins, she will continue to lay for a long time, or until she becomes broody. Pullets hatched last spring will not moult until next year, as only the hens will moult in summer, but a pullet hatched very early—about January or February may moult, though the chances are, that she will not do so until next year. Clean, dry quarters should be provided for the hens that are moulting, and lice must be kept down, as the hens that are moulting will quickly succumb to lice, owing to the debilitating effects of the process. As to the males, they should have been sold off long ago, as it does not pay to keep one that is moulting, unless such male possesses some characteristic that is sought, and the sooner the males are sent to market, the higher the prices they will bring.—*Farmer's Guide*.

104 Holsteins For Sale.
Young Bulls and Heifers by the richly bred **Royal Paul.** Prices right for quality. Show animals, all ages, bred for butter makers.
DELLHURST FARM, Mentor, Ohio.

HOLSTEIN-FRIESIAN CATTLE
Owned by **JONES & RANDALL, Hustisford, Wis.** 100 head to select from. From families rich in butter fat. Herd now headed by Barron Paulina De Kol. Stock for sale. Prices reasonable.

HOME FARM HERD.
Headed by Jewel of Home Farm, Sweepstakes Holstein-Friesian Bull Trans-Mississippi Exposition Omaha, Neb. Seventy-five head to select from. **W. B. BARNEY & CO., Hampton, Iowa.**

MEADOW LAWN HERD Holstein-Friesians.
Herd headed by **Sir Brookside De Kol.** Choice young stock for sale. Come and see them. C. W. HARRISON, Ringwood, McHenry Co., Ill.

Holstein-Friesians
MECHTHILDE BULLS FOR SALE.
Address **M. W. BARDEN,** Portage, Wis.

McGEOCH FARM Holstein-Friesians.
Herd headed by Gem Pietertje Hengerveld Paul De Kol and Johanna Paul Colantha. A few young bulls, 3 to 7 months old for sale at bargain prices. H. B. DAGGET, Mgr., Lake Mills, Wis

CAREME
Is the 4th highest butter cow in Holstein history. Her butter record is 35 lbs. 9 oz. in 7 days, 100 lbs. 12 oz. milk in 1 day, 2,591 lbs. in 30 days. Winner of first prize at New York State Fair, 1888. Breeders' Gazette says: "Greater things are expected of her than she has already done, she is hard after Mechtchilde." Valley Mead Farm boasts to contain the best of everything, so it possesses also three daughters of Careme, which have been great prize-winners, and many grand-daughters.
VALLEY MEAD FARM, Monticello, Wis.

Markham Manor Farms. Simonsville P. O., Andover, Vt.
Holstein-Friesian cattle bred from the most fashionable butter families, individually large producers, and of the most approved show form. The herd contains seven daughters of Sir Netherland Soldene Clothilde, No. 18390, H. F. H. B., the most remarkable show bull of recent years. Also large English Berkshire Swine from noted prize winning and imported stock. Write for description and prices to **J. A. THORNTON,** Mgr., **Simonsville, Vt.**

OAK GROVE HERD H-F. Cattle.
Cows, Heifers and Bull Calves For Sale.
C. H. Stevens, Jefferson, Wis.

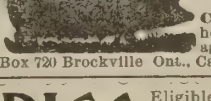
High Test I offer the grand young bull Prince Mercedes DeKol, whose 4 nearest tested relatives have an average equivalent record of 24½ lbs. and 4.14% fat, and have won 1st, 2d, and two 3d prizes in H.-F. Offic'l Prize Contests. Others extra good. MALCOLM H. GARDNER, Darien, Wis.

130 Holsteins. First prize herd at Trans-Mississippi Exposition at Omaha. 1st and 2nd on aged cows and 1st. on two-year-old heifer in the seven day butter test, open to all breeds at same Exposition. Three cows in this herd have produced the most butter in seven days of any cows ever officially tested. A score of others nearly as good. Our richest bred bull calves are taken young. Sons of De Kol 2d and Netherland Hengerveld head the herd. Animals of both sex and any age for sale. Write stating just what you want. HENRY STEVENS & SONS, Lacona, Oswego Co., N. Y.

Guernsey Bull For Sale . . .
We have a Guernsey Bull, **Von M. No. 4717,** for sale. Three years old and of excellent breeding. Good reason for selling. Price $65.00.
Address, **THE JOHN HEIN CO., Tony, Wis.**

REGISTERED
GUERNSEY BULLS
We offer several well-bred young Guernsey Bulls, dropped in April and May, '99, at **$25.00 Each,** registered and transferred. They are handsome and well grown and grandsons of Gold Bound No. 2726, bred by Mr. Levi P. Morton and sired by Imported Midas 2003. Dam, Imported Lady Antornelle 2d, 3680. **M. B. ROWE & CO., Fredericksburg, Va.**

Riverside Guernseys,
CHAMPION Herd
AT NEW YORK STATE FAIR,
1898, in competition with the leading herds of the country, won eight firsts and sweepstakes. Young stock by **COMUS,** sire of most of the winners, for sale. Thoroughbred Poultry—the best egg-producing and general purpose varieties—Leghorns, Wyandotts, Buff Ply. Rocks, Houdans. Send for circular. Stock for sale. **J. FORSYTH,** Riverside Farm, **Owego, Tioga Co., N. Y.**



ROSENDALE
GUERNSEYS
Our herd has won first prize at the Wisconsin State Fair every year since 1894, and also won first at Minnesota State Fair and at the Trans-Mississippi Exposition in 1898. We keep only 400-lb. cows. Tuberculin tested.
GEO. C. HILL & SON, Rosendale, Wis.

"Florham" Guernseys.
First Prize Herd wherever shown, viz: New York State Fair, 1895 and 1897; Bay State Fair, 1895; Inter-State Fair, Trenton, N. J., 1895 and 1897; Madison Square Garden, 1895; New Jersey State Fair, 1897. **J. L. HOPE,** **Farm Supt., Madison, N. J.**

GUERNSEYS!
84 Cows averaged 399 lbs. of Butter each in 1898.
Some Choice Young Stock For Sale.
ELLERSLIE STOCK FARM, Rhinecliff, N. Y.

AYRSHIRES **Finely Bred** and from the very best families. Stock for sale, bred for milk and butter qualities. Also fine herd Chester White Swine. Correspondence solicited.
FRED TSCHUDY & SON, Monroe, Wis.

Pedigreed Poland Chinas of the BEST feeding strains. Pigs at weaning $5 to $7. Also Mammoth Light Bramah fowls. K. S. HAWK, Mechanicsburg, O.

Pure Bred **Tamworth Pigs,** Bacon curers choice. Pure Bred **Ayrshire Cattle,** largest imported herd in America. Stock all ages for sale, R. G. STEACY. Box 720 Brockville Ont., Canada

PIGS Eligible to REGISTRY, and First Class Stock, at Reduced Prices. **Chester White, Berkshire, Poland-China and J. Reds. Thoroughbred and Grade Guernseys. Also Poultry. W. B. HARVEY, West Grove, Pa.**

Cedar Hill Notes.

Heat and Milk Flow.—Fall Feed.—Cream in Hot Weather.

ED. HOARD'S DAIRYMAN:—Forty-six pounds shrinkage in our herd's milk in twenty-four hours, from excessive heat, is what our daily milk record shows for the date of August 13th.

Feed, care and other things count for naught in such a case. We must put up with the loss the best we can. In our case it puts us in bad shape, as we must make 210 pounds of butter weekly, to fill a ten months' contract. The party of the first part don't care whether it is hot or cold, just so he gets the stipulated amount of butter.

Some good rains have started blue grass to growing once more, and in case we have regular rains, fall feed will be abundant. We have sown several acres of crimson clover, turned under our pea stubble for it. This is our first experience with this plant. Rape with us is a very fine soiling crop; it stands the drouths well and yields an immense amount of good feed.

We have our foundation partially completed for second silo, and the corn will be ready about the first of the month for cutting. The staves for this silo are twenty-six feet long, of spruce. We have given them a good coat of tar on all sides while down, which will insure long life when built.

Will the DAIRYMAN readers tell us what self-binding corn harvester to buy, and are they a sccess—very heavy corn? We are contemplating buying a Deering.

During these very hot days our method of handling cream is giving good results. Our butter goes from churn to worker in soli body, and points at once as well as in cold months. As before stated, we use a channel vat, ripen cream twelve hours, then hold twelve hours with ice and brine; then churn at 60 or 62°. Feeding cows two pounds of cotton seed meal, daily, each. Our cream makes four pounds of butter per gallon, and requires thirty-five minutes to churn.

We are now enjoying a visit from a Waukesha Co., Wis., dairyman, and even if he does come from a dairy state and county, we are giving him some surprises in methods and herd work. BUFF JERSEY.

The DAIRYMAN cannot undertake to decide upon the merits of different makes of farm machinery.

Haymaking.

Practically all kinds and species of pasture plants become hard as they grow old, and rapidly deteriorate in nutritive value and digestibility with age. Moreover the maturing of seed very seriously lessens the vitality of the plants by imposing a heavy tax on them; to such an extent, indeed, is this the case that some of the more sensitive and small grasses disappear it permitted to seed while they are young. The loss of vigor entailed necessarily lessens the aftermath, and probably adversely affects the crops of the following year, besides encouraging the growth of weeds. It is our experience that seeding for several years in succession eliminates quite a number of pasture plants, the gaps which would otherwise be left, being quickly filled up with indigenous and often worthless species. Hence the grass crop should be cut early in the season, and before any of the plants have produced seeds. There are two objections that can be urged against early cutting, but fortunately both are of small moment. Firstly, the yield may be slightly smaller, but against this must be set the increased bulk of aftermath, which more than compensates for any deficiency; and, secondly, the produce is liable to shrink in drying, proportionately rather more than would older vegetation, which is naturally stiffer and more fibery. As a matter of fact this second objection is hardly worth consideration under any circumstances.

As illustrating the depreciation of pasture grasses with age, the following figures are useful: When in full and early leaf the nutritive value of cocksfoot—which is, by the way, certainly the best and most nutrttive of all pasture grasses—may be represented by the numeral 137, falling to 100 when the plants begin to bloom, to 87 after bloom, and to 70 when the seeds ripen. That is to say, cocksfoot loses approximately half of its net value by ripening its seeds. Again meadow foxtail, another very valuable species, has a full-leaf nutritive value of 148, depreciating to 106, 89 and 81 at respectively flowering, after flowering and maturing of seeds. Parallel results are obtained by analyses of tall fescue, fescue, yellow oat grass, timothy, rye-grass, hard fescue and rough-stalked meadow grass. Briefly, then, one loses in quantity by too early cutting, and in quality by too late mowing; while late cutting is also prejudicial to the aftermath. The time of mowing is, however, to some extent, dependent on the season and crop. For instance, it is occasionally necessary to cut early to prevent specially noxious weeds present in the herbage forming seeds, and also when the crop is laid and so liable to rot. Again, late mowing is often unavoidable in very wet seasons, since hard and fibery hay—bad as it may be—is better than that injured by being made in excessively wet times. Lattermath hay is generally considered superior to ordinary hay in nutritive value; but the succulence of autumn growth and the heavy dews of late fall combine to render its making so precarious that we advocate its much more extended use as silage.

DRYING BY SUN-HEAT.

It is customary to spread hay out in the sun to dry as soon as it has been cut, the produce being turned frequently, and carried to the stock from the cock without breaking it out, and in the evening made up into cocks, which are spread out again when the dew has evaporated on the following morning. A very heavy dew might cause serious injury were one to occur, so that the advisability of cocking the hay the first night should be apparent. The tedding machine can be freely used during the second day if the weather be favorable, and light or medium crops, which do not contain disproportionately large quantities of leguminous plants, may be carried the evening of the third day as a general rule. When the weather is continuously wet the grass must be left as cut, unless—and this is much the wiser plan—it be carried directly to the silo and converted into ensilage. The leaves of all leguminous plants become brittle as they dry, and if handled over-much they break off, a great part of the nutritive value of the whole crop being thus lost. The produce therefore of this class of plant should be turned as little as possible and only by hand in the swathe. To early carrying is injudicious, because the presence of much sap in the plants induces heating in the rick, sometimes even actual firing.

The old method of testing the condition or succulency of the crop by twisting a few stems into a rope is a good and reliable one. If moisture exudes it is yet too early to carry the crop. Experiment proves that from twenty-five to forty per cent of the dry substance is washed out of clover hay by rain, so that partially dry hay ought always to be made into rather thick or high cocks when rainfall is expected, so that the least possible quantity of water may have access to it. The hay from cocks that have become heated in this way, dries very rapidly when spread out in dry weather.

CLOVER HAY.

For marketing purposes greenness is desirable, it being justly regarded as an indication of well-made hay, but the color is not of much consequence if the produce is to be used at home. The brown clover hays so frequently seen, are specially made with the object of obviating the necessity for frequent turning and consequent loss of leaf, while sacrificing the color. This quality of hay, which is in every respect as nutritive and wholesome as green hay, is made by drying the plants in the sun, turning them once only during the operation, until about two-fifths of the water contained in them is evaporated, that is to say until they are nearly half-dried, when they are made into cocks.—*Journal of Agriculture*, Ireland.

A GOOD THING ONCE MORE.

Every volume of HOARD'S DAIRYMAN contains some things that ought to be published from two to three times a year, even for the benefit of old readers. Then, again, the subscription list is all the time increasing, and new readers are coming into the circle, so that a valuable bit of experience is still more worth repeating. On page 214, of the issue of April 22, 1898, is printed the valuable experience of A. M. Stevens, of the state of Washington, in removing obstructions from the teats of cows. It is so full of practical wisdom that we republish it in this number:

That obstructed cow's teat seems to be legion, judging by the many inquiries I see in the DAIRYMAN concerning them. In the last number of HOARD'S DAIRYMAN, page 151, is one stopped up with a lump in it. Now, at the risk of getting a scolding, we will give a little of our experience with obstructed and damaged teats. No. 1: Cow's teat became tender, hard to milk, inflamed, and only with hard pressure could a very fine stream of milk be drawn; end of teat scabbed over. At this stage, I had the milker turn the cow over to myself. As the quarter was hot and swollen, bathed it with turpentine and camphor, shut the feed off the cow; tried one of those rubber milking tubes, but the teat was so much inflamed, could not insert it in the teat without great force; so abandoned the trial, wrapped the teat up in an ointment made of spermaceti, gum myrrh, and olive oil, and let it go for three days; milked the other three teats regularly, and rubbed the affected quarter gently; second day rubbed the quarter with fish oil, and when we unwrapped the teat, found the swelling in teat gone, and the end of teat free from scab. Could only get a little water out of it; on examination found a lump about one and one-half inches from the end of the teat in the milk duct.

Well, we took a piece of fine spool wire and made a loop, something like the diagram

perhaps a little wider at the looped end, inserted the looped end, which was perfectly smooth, into the teat until it passed above the lump, turning it round and round, moving it up and down gently, until we got the lump in the loop and pulled it loose, then milking, with the wire still in the teat, very gently, we were rewarded with catching the nodule in our hand. It was, perhaps, as large as a grain of wheat. Well, we milked the teat, same as the others, for several days, got nothing but a thin, watery fluid out of it, but in perhaps a month or six weeks' time, the quarter gave nearly the usual amount of milk, and, at the next freshing of the cow, it was all right.

Case No. 2. This was an injury from being stepped on by another cow; teat was badly bruised, and quarter soon caked, and could get milk with difficulty; teat too much inflamed to insert tube; bathed quarter with aconite, and wrapped the teat up same as number one.

The teat closed so we could get no fluid out of it. Kept it wrapped up until the inflammation somewhat subsided, then took the wire loop and inserted it gently, found the teat closed with a cheesey substance, perhaps dried pus or gargety milk, but effected an opening through it with the wire loop and got a small quantity of watery fluid from the teat. We opened it with the loop at each milking for a few days, until it became all right, and at next freshening was as good as ever.

Case No. 3. This was a clean cut about three fourths of an inch from the end of teat, perhaps done by a barbed wire; teat cut fully half off, and milk came ou of the wound in attempting to milk it. It was an ugly looking affair, and we concluded the quickest way to treat it was the best. So we got our pruning shears, sharpened them, and cut the teat square off at the wound, wrapped it up and let it go for three days. We then bathed the quarter in fish oil and iodine, shut the feed off the cow, dressed the teat every three days and milked it very gently. It healed remarkably quick, the milk returned in the quarter, and to-day is as good as ever.

A tube or plug was not available in either of these three cases; in two of them the wire loop was used successfully, in the third, it was not used or needed. All three cases had a successful termination, and unless something better is invented, will use it again if circumstances require it.

A. M. STEVENS.

Kittitass Co., Washington.

Illinois Jersey Breeders' Exhibition.

ED. HOARD'S DAIRYMAN:— Will you kindly make mention of the following in your paper: In order to encourage the Illinois Jersey Breeders to make an exhibit at the State Fair to be held in Springfield the 25th–30th of September, the Illinois Jersey Cattle Club offers the following premium: Jersey Breeder's young herd, to consist of one male and four females, under two years old, the females to be bred and owned by the exhibitor, and the male to be owned by the exhibitor; First prize, $20.00, second prize, $10.00, and third prize, $5.00. Competition open to all Illinois Jersey breeders.

Tamaroa, Ill. WALTER R. KIMSEY, Sec.

It is reported that at the Chicago packing houses, the meat of the average steer brings about $40, while the product not eaten, will bring about $55, divided as follows: Hide, hair, horns and hoofs, $25; fat, blood, sinews and bones, $15; other miscellaneous wastes, $15. These are carefully graded, and sold for different purposes, even the contents of the paunch being used to make into cardboard. The horns are worth now $150 a ton, owing to the prevalence of dehorning. A yearly count showed about one pair of horns to each six steers. The saving of material formerly wasted at the abattoirs, cheapens the cost of meat to the consumer, and still adds to the profit of the packing companies.

Gluten Feed is used by nearly all successful dairymen, and has become a necessary article for any dairyman farmer who wishes to keep pace with the successful men in his line of business.

Gluten Feed increases the flow of milk, improves the quality, keeps the cattle in the best possible condition—in fact, helps you make more money out of your dairy. This is not cheap talk. We mean business. Gluten Feed is all and more than we claim for it, and, best of all, a trial proves it. Sample of Gluten Feed, Milk Talk Pamphlet, and circular illustrating the "Value of Butter Fat in Milk," all FREE if you address

THE GLUCOSE SUGAR REFINING CO.,

DEPARTMENT H. The Rookery, CHICAGO, ILL.

COAL TAR BUTTER COLOR

Is prohibited by law in Austria as detrimental to the public health. Over one-half the butter in America is colored with coal tar dye. Do you want to know how to test it? Send to us for the material for making the test and we will mail it to you free of charge.

Thatcher's Orange Butter Color

Is a pure vegetable color, free from deleterious substance. It gives butter

THE DELIGHTFUL JUNE TINT

So well known among users of high grade butter. It is healthful. For sample bottle send to

THATCHER MANUFACTURING CO., - Potsdam, N. Y.

Prosecuting the Oleo Dealers.

The Illinois Dairy Union, which is an auxillary of the National Union, has inaugurated a warfare on the dealers in oleomargarine in Chicago.

Detectives employed by the Dairy Union have been going about among Chicago grocery stores making purchases. They have called for the best butter.

Seventy-eight of these purchases have been analyzed and seventy-four of them have been found to be plain oleomargarine. In every instance the price paid was from seventeen to twenty-three cents, while the retail price of good creamery butter has ranged from nineteen to twenty-five cents. The oleomargarine, according to the Union, costs the retailer about six cents a pound, while the ordinary profit on butter is but two or three cents a pound.

Secretary Knight declares that the revenue laws regarding the stamping of every retailed package of oleomargarine and the displaying of a license issued by the government are openly violated.

During the past few months the demand for milch cows has fallen off at an alarming rate and the demand for beef fat has increased in proportion.

Ten years ago the sales of oleomargarine amounted to less than 25,000,000 pounds. For the fiscal year just ended the sales have been 87,800,000. The dealers have cut down their orders of butter, preferring to get the immense profit in oleomargarine in preference to the small one in butter.

Dairymen Need Good Roads.

It is often a surprise to us that patrons of cheese factories and creameries do not rise up in their might and demand good roads at any cost. In sections where co-operative dairying has been carried on for years, we often find our very worst roads, which during the spring and fall months must be almost impassable. To haul milk five or six miles over such roads, would to many seem almost an impossibility, but still it is done and the same thing continues year after year.

If the bad roads in such sections were replaced by roads that would remain good at all seasons of the year, the patrons of the factories in these localities would be able to get their milk hauled very much cheaper and would get a better quality of product out of the milk when delivered. We speak advisedly in regard to this latter contention. There is no doubt that milk is often materially injured for either butter or cheese making by being churned or agitated, as it is when hauled half a dozen miles on some of those almost bottomless or rough, rocky roads.

In this goodly city of Toronto there are block-paved streets so bad that to ride on them gives one a sensation not unlike a quick tumble down a stairway. A year or two ago, before the block pavement was replaced by asphalt, on one of the streets the city milkmen could not drive because the milk would be churned into such a state that their customers would not take it. In order to retain his trade one milkman was compelled to leave his wagon at the end of the street and carry the milk by hand for a couple of blocks If hauling milk a block or two even, on this rough pavement would have such an injurious effect on milk for family use only, what must be the effect when milk is subjected to similar treatment for an hour or two when on the road to some creamery or cheese factory? Is it not reasonable to suppose that its quality will be very much injured for either butter or cheese making?—*Farming.*

Milk for Poultry.

On every side we hear the warning words "Don't feed any sour food," and in the next moment comes the advice to "give them all the milk, both sweet and sour they will use." Slop may be the natural food for hogs, but it is not for hens. Milk as a fluid, either sweet or sour, is very good for "mixing ground food for fowls," but when placed in pans for them to eat or drink it is more of an injury than a benefit, for the reason that it soils the plumage and taints the ground, thus attracting the flies and other insects, which bring with them more injury than the good the fowls have received from the milk. One attribute of success, namely cleanliness, is almost an impossibility where milk is used as a drink or fed in pans to the fowls. What can be more disgusting than a lot of half grown chicks besmeared with sour milk and covered with flies! And to add to their sorry plight down comes a misty rain, completing their uncanny appearance.

I have often seen the feeding ground of a lot of growing chicks covered with sour milk and flies, the ground well beaten down with the patter of the feet of both ducklings and young chicks. What can be more disagreeable than the odor of this feeding spot after a shower has been driven away, and the warm sun shines upon the ground and proceeds to bring to life the deposit of the many insects drawn to the locality by the besmeared condition of the ground? And those who care for these fowls wonder why gapes, diarrhœa and cholera come to their flocks. None so blind as those who will not see. Why not get all the advantage of the milk by using it to mix with their ground food instead of placing it in pans for them to run through and paint the ground to their own destruction?

Cleanliness is the one great thing with poultry. No one can begin to keep their surroundings in even half-way condition, who places pans of milk or slop of any kind for fowls. Many writers advocate the plan, and tell us in glowing terms of the benefits to be derived from this feeding of milk as a slop to poultry. If the benefit is to come to them from the milk, use it each day to mix their ground food with, and feed it to them in boxes or troughs, not upon the ground, and provide feeding space sufficient for all to feed at once. Where no ground food is provided for the poultry, better give the slop to the hogs.—*Country Gentleman.*

Liming Soils.

(Press Bulletin.)

Lime is a necessary plant food but being far less often deficient in soils than nitrogen, phosphoric acid or potash, it does not receive like attention from farmers, especially as such fertilizers as acid phosphate, bone meal, and ashes contain it in large amounts.

Chemical analysis shows that while lime accumulates in the soils of very dry regions, it leaches out of the soils of a moist climate like that of Tennessee. Although Tennessee soils are derived largely from lime rocks, they are often poor in lime as is proven both by analysis and by practical experience. This is strikingly illustrated by the "red soil" of the Highland Rim, which, though derived from limestone, is not productive until limed and afterwards improved with cow peas and phosphates, when it becomes a first-class wheat land.

This article has special reference to common quick lime, which is generally easy to get and the most efficient form when properly applied. There are at least four important conditions under any one of which highly beneficial results would be expected to follow its use; first, when a soil is deficient in its supply of lime for plant food; second, when there are abundant supplies of nitrogen, potash and phosphoric acid in the soil, but so locked up as to be largely unavailable for plant use; third, in case of sour or acid land; and fourth, lime acts strongly to lighten stiff and heavy soils.

Chemically, the chief results of liming are the changing of unavailable plant food to available, and the neutralizing of injurious acids.

By holding the finer particles together, lime makes a compact soil flocculent and porous, and thus counteracts tendencies to bake and to dry out. It also prevents the excessive leaching of loose soils. Lime nourishes, also, some of the most useful soil bacteria, while it is destructive to injurious insects, fungi, etc.

Among the evil effects of lime are its tendency to set free ammonia, to make some soils too open, and, as an exception to that stated above, it is said to nourish the organism which produces scabby potatoes. Soils are often found, too, on which it produces little change, particularly those that have been well dressed with phosphates.

As its merits usually far overbalance its demerits, every farmer would do well to test it under such conditions that its true effect can be plainly seen, such as by liming one part of a uniform field and by leaving the other unlimed, both parts receiving neither different treatment nor other fertilizer, For this test, wheat, oats, cow peas and clover give good indications.

The amount applied depends on the kind of soil, whether heavy or light, rich or poor. For a heavy, clayey soil, or for a very rich soil seventy to eighty bushels per acre is a reasonable amount. For very light and for rather poor land twenty to thirty bushels are sufficient at the outset. The humus supply in such land should be increased by stable manure, cow peas, or the like, or the lime may do harm. As many as three hundred bushels to the acre have been used with advantage on very stiff clay, while as a rule very poor land should not be limed.

It is well to bear in mind that the chief action of lime is to improve the mechanical condition of soils, and is therefore to be applied by the ton rather than by the pound. Forty to fifty bushels per acre is given as an average amount, which, if we allow eighty-five pounds to the bushel of unslaked lime, is 1¾ to 2¼ tons.

Immediately after burning, lime has the composition, calcium oxide, which readily unites with water to form calcium hydrate or slaked lime, the best form for general application. When exposed, this slaked lime slowly combines with the carbonic acid of the air, forming the same compound as in the limestone before burning, but in a very fine state of division. As this is far less energetic than slaked lime, the following method of application is recommended; freshly burned lime is put in heaps at convenient distances for distribution; forty pounds, twenty-one feet apart each way, would give two tons to the acre. To prevent the ready access of air these heaps should be covered with soil. If the ground be moist the lime will fall to a fine powder in a few hours; if it be a dry time a little water can be used. Just as soon as it is slaked to a powder it should be spread and plowed, or preferably, harrowed under. It is important that the day for spreading be dry to prevent the formation of lumps.

As lime frees ammonia and also renders soluble phosphoric acid, insoluble again, care should be taken not to apply it at the same time as other fertilizers or stable manure. The fall is the best time for the application of any form, caustic lime in particular.

Calcium sulphate, commonly called gypsum or land plaster, is another form of lime which is much used. While of value, it is not so highly thought of as the quick lime. Its chief merit seems to be to make available certain insoluble forms of potash already in the soil. In this way its superior effect when applied to clover is accounted for. It is best to apply it some months before planting, or as a top dressing. It is frequently used at the rate of two hundred to three hundred pounds to the acre. As a rule, it does not pay on very poor land and is not advised where high farming is practised.

Often the effects of lime can be seen for years while a fresh application every five or six years is frequently profitable. The present tendency is to lime oftener and to apply less at a time.—*Tennessee Experiment Station.*

Beware of Cheapness.

BEWARE of the butter color that an agent claims to be *"just as good"* as W. R. & Co.'s Improved, but which he offers at a cheaper price.

There is not and never has been a color *"just as good."*

Why should any one be obliged to offer a color at less price if it is *"just as good."*

While cheap colors may be cheap in price, they are expensive to use.

ILLUSTRATION.

Among those manufacturers who use our columns each year in placing their claims before the public, few are better or more favorably known than the E. W. Ross Co., of Springfield, Ohio. These people are the manufacturers of the famous Ross Ensilage, Dry Fodder and Feed Cutters. These machines have long been before the public, and so far as we know have always given good

satisfaction. They have been improved from time to time to keep pace with the demand and the changed conditions. Accordingly, therefore, all the Ross power cutters can be equipped at small additional cost, with an extra cylinder especially designed for shredding fodder. They are made in a great variety of sizes, from six inches to forty-eight inches. They are strong, well made machines, and are backed by the long experience and good reputation of their makers. Write these people for catalogue, and treatise on ensilage. Please say that you saw this notice in our paper.

American Butter in England.

To Mr. Arthur Dodge, the Washington correspondent of the Milwaukee *Sentinel*, we are indebted for the following interesting summary of the forthcoming report of Major Henry E. Alvord, Chief of the Dairy Division of the Agricultural Department at Washington. The report recounts the experiments that have been made by the Secretary of Agriculture in promoting the sale of American butter in England.

In commenting upon the results obtained in these experimental exports, Maj. Alvord said: "The apparent indifference of American producers of dairy products is one difficulty in the way of establishing a good market for high-class dairy products of this country abroad. We have observed that our producers pay little attention to the export trade unless there is an over production in this country. In order to be successful in building up a foreign market our exports must be continuous. The English merchant does not desire to build up a trade on a certain line of goods, and suddenly find that the supply is shut off. Inquiries are coming to the department from English buyers asking names of American creameries that can be recommended to furnish regular shipments. Only last week," said Maj. Alvord, "we received a communication from an English firm asking reference to a creamery that could furnish 600 tubs of high-grade American butter a month."

The importance of the British market to American exporters of butter is shown by the fact that in 1897 English buyers purchased abroad $77,000,000 worth of butter. In fact, British purchases of butter from the outside have doubled during the past ten years, and last year the quantity imported by the United Kingdom aggregated 3,500,000 hundredweight. The latest figures on British importations of butter show that the United States leads Canada on butter sales to the United Kingdom by 154,000 hundredweight against 109,000 hundredweight sent by Canadian exporters. Denmark continues to be the chief source of supply for butter imported into Great Britain, the Danes sending 1,300,000 hundredweight into the United Kingdom last year. All other countries combined sent 1,600,000 hundredweight. The importance of this export trade is further shown by the fact that the American exports of butter to all countries last year aggregated 20,000,000 pounds, valued at $3,263,000.

NORTHWESTERN DAIRY PRODUCTS USED.

The experimental exports by the department included lots of high-grade creamery butter from Fort Atkinson, Wis., Strout, Minn., Big Stone City, S. D., and various points throughout the dairy districts of the West. The department paid for the butter used the regular market price, at the time of shipment. The exports were generally in packages varying in size, form and treatment. In the general trade of Great Britain it was found that packages holding from fifty to sixty pounds are desirable. It was found that double linings for packages of paper parchment and paraffine applied hot to close the cracks and joints in the wood were desirable. The department trials also included butter in prints, and also packed in tin and paper boards, sealed suitable for ocean voyages. Thorough analyses were made of butter selected in the open London market. The summary of the results obtained as set forth in the report ends with these significant observations:

DESIRE TO EXPERIMENT FURTHER.

"American butter can only be introduced abroad successfully and establish a demand for it, with the full recognition of its merits, after a period of persistant effort. English merchants of standing and in control of reliable, high-class trade must be interested in the effort, and induced to act as agents for butter sales. These agents must be regularly supplied with butter, uniform in quality and quantity, and suited to the markets they represent, for seven or eight months of the year. The department cannot establish this foreign trade in high-class butter or even begin it, but it may do something toward ascertaining the conditions which control such trade and assist in making them known to many interested parties." The result of the trials, the officials conclude, justify a repetition of the experimental shipments upon an enlarged scale and in a broader field, and to include besides butter, other perishable farm products which this country has to sell.

GAINS AND LOSSES ON SALES.

Some difficulty was experienced by the department in securing refrigerator space on American trans-Atlantic lines, and better results were obtained on shipments over lines between Montreal and London. Under the fostering care of the Dominion government seventeen steamers sailing from Montreal have been fitted with refrigerators. The cost of transportation on these experimental exports ranged from 1¾ to 3¼ cents per pound of butter, net weight. The average from Iowa was less than 2½ cents, and from Kansas 2¾ cents. Time of shipment required from creameries in Wisconsin, fourteen days; Minnesota, sixteen to eighteen days; South Dakota, seventeen or eighteen days, which allows for handling in cold storage and reshipment from time of loading at the creameries, to placing on the London market. The general opinions expressed by British consumers were highly commendatory of this American butter, although where its supply was unknown, they believed it to be the "Best Dorset" (English) or Danish butter, the favorable brands in the high-class retail trade for cured or salted butter in London. By special efforts the department secured the co-operation of dealers to advertise by placards "Selected Creamery Butter From the United States." To sell it readily as such they were obliged to place the price rather lower than that of butter of greater reputation, but admitted to be no better, on sale at the same place. Twenty-four and twenty-six cents were the respective prices of the two grades.

The purchases for these exports were made during April and October, and ranged from thirteen cents, the lowest price paid in Kansas in July, to twenty-five cents, the October price paid in Connecticut The London sales ranged from 15¼ cents in May, to 21¾ cents in October. Butter from Minnesota and Ohio sold at a net profit of 2¼ cents a pound, from Kansas at two cents profit, and from Wisconsin at about one cent profit. The average cost of these lots was 14¼ cents, and the average selling price 18½ cents. Following is a sample expression from wholesale merchants in London on, the American shipments:

SOME BRITISH OPINIONS QUOTED.

"We have carefully inspected your American butter, and find the quality and condition better than any of the kind we have yet seen, but it contains too much liquor, which runs when defrosted." Another said: "I have inspected samples of butter and consider the quality to be very fine. There is but one fault that I can find, and that is the firkins contain too great a percentage of water. I am sure this class of butter would be taken up very largely by the consumers in London and suburbs, if it could be shipped in large quantities regularly throughout the season, and the quality kept equal to this lot. I should like to have 2,000 to 3,000 packages a month." A retail dealer said; "The package of American butter was in every way satisfactory. By this I mean that it was well made, carefully packed, and possessed of the very best keeping quality. The flavor was agreeable, and the amount of salt just about right to suit the general English taste." Another said: "For the London trade it savors too much of the Irish 'twang'; is a little too salt and the color too high." The general expression by consumers was that the American butter was excellent. One consumer said: "It came, saw and conquered." One said: "It is very good; similar to Irish creamery, but I think the quality superior. It was rather light in color; otherwise, it was, in my opinion, excellent."

WHAT THE BRITISH MARKET DEMANDS.

The experiments by the department induced the officials in charge to conclude that "The demand for butter of good quality in Great Britain, and the steady increase in this demand, offers a market for large quantities of the best creamery products of the United States." It is further observed that there is no reason why butter from this country should not compete successfully with Canadian and Australian butter in the markets of the United Kingdom, at all seasons of the year. The local requirements of markets in different parts of England and Scotland will have to be further studied, and care taken to prepare butter to meet the varied tastes. As a rule, the British demand a butter freer from brine, more waxy in texture, firmer, or "better in body" than the average "extras" of the American creamery. For export butter, more time and care in making and packing are essential; less attention to securing a "quick high" flavor and more attention to good body. The flavor may be mild, rather slow in development, but should be "clean" and uniform month after month.

CARE IN MATTER OF SHRINKAGE.

The report further says that it seems probable that pasteurizing cream and the use of pure cultures for ripening will be well adapted for making successful export butter. The color in British markets is permitted to vary somewhat with the season, but very little artificial coloring is desirable at any time. A natural grass yellow is generally regarded as too deep. Some English markets prefer butter

WHO IS TO BLAME

Women as well as men are made miserable by kidney and bladder trouble. Dr. Kilmer's Swamp-Root, the great remedy, promptly cures. At druggists in fifty cent and dollar sizes. You may have a sample bottle by mail free. also pamphlet telling all about it and its wonderful cures. Address, Dr. Kilmer & Co., Binghamton, N. Y.

very pale, or a slight shade of straw color. As to salt, the tendency is to use less. It is also noted that shrinkage must be provided for. The usual loss is about one-half of one per cent on the net weight. The department investigations were not conclusive on this point, but if fifty-seven pounds of weighed butter is packed in an export box, the net weight in any market of Great Britain within a month's time, will be pretty certain to exceed fifty-six pounds. It is necessary to allow for shrinkage of weight on every small package, as the London market laws require full weight in all commodities at retail, and are strictly enforced.

Corn Fodder in August.

With the approach of dry weather, many pastures are unable to supply food for good milk production, and with continued dry weather, the falling off in milk yield becomes a serious matter. It is not economy to wait until the pastures are poor before helping the cows to procure better food. There is a hesitancy on the part of many, who are raising corn fodder, to feed any of it during the summer, because they fear that they will not get full value for the crop. The doctrine is: Let the cows get along the best they can and let the corn fodder mature.

Corn fodder in its early stages of growth, while it contains a large per cent of water, contains valuable milk stimulating nutrients. The dry matter of corn fodder in its early stages of growth, is more nitrogenous in character, and therefore more suitable for milk stimulation, than matured corn fodder. Of course less weight of dry matter per acre is secured, but then there are no heavy losses from corn stalks that are so hard and woody that they cannot be eaten by stock. When the pasture becomes barren, corn fodder, with a little bran or grain, will keep up the flow of milk and prevent the creamery checks from being cut in halves. It is better economy to feed green corn fodder in August to keep up the flow of milk, than it is to feed dry, bleached corn fodder in December, when the cows are demanding more food to keep their bodies warm, and are possibly not producing milk. A field of corn fodder in August should not be considered too good to feed.

What does corn fodder in August contain in the way of nutrients, and what is the cow able to get out of the corn fodder? We must, of course, recognize that there is a great difference in corn fodder. That which is grown on a farm where the land is well cultivated, manured, and the crop properly cared for, is at least one hundred per cent more valuable than stunted, sickly, yellow corn fodder, half starved and grown on poor land. A horse that is well fed can pull a bigger load than a "plug." So can corn fodder that is well fed, produce a better yield of milk than "scrub" corn that is half starved. Green corn fodder contains from 85 to 88% of water—about seven-eighths water and one-eighth dry matter. If we were to remove the water and consider only the dry matter, we would find from eleven to fifteen per cent of protein. It is this material (protein) which gives the fodder its value. A cow has no objection to eating fifty or sixty pounds per day of green corn fodder, and if it is good fodder she gets over a pound and a quarter of protein. If the cow were compelled to search the pasture and get a few mouthfuls here and there, she would not get very much protein, and the flow of milk would fall off seriously. Pure corn fodder, valuable as it is, however, should never be fed alone, but along with a fair amount of bran or grain, it gives excellent results as a milk stimulating food.—HARRY SNYDER in *Farm Stock and Home.*

Cement Concrete Structures.

Mr. Isaac Usher, of Queenston, Ont., in his Institute talks gives a few of the essentials and methods in the following words: "In building concrete structures, clean gravel only must be used. It must not be earthy, loamy or sandy. It must not be too fine; in fact, the gravel should run in size from a wheat grain to egg size. If gravel of this sort is used, about eight barrels of gravel are used to one of cement, and it makes a stronger wall than very fine gravel and cement, equal parts, and is also more economical. Cement is put up in jute and paper bags. The jute bags hold two cubic feet of cement. The preparation of the concrete mixture is somewhat as follows: A bottomless box, three feet by four feet by one foot high, is used, on a large platform where the mixing is done. The box is placed and half filled with gravel, then half the cement to be used is added; then to the box is added as much more gravel, and then the balance of the cement. The proportion here is one to six—twelve cubic feet of gravel and two cubic feet of cement.) *This is mixed thoroughly* DRY! When thoroughly mixed, water is added gradually. About three to four pails of water is needed for the above quantity, varying a little according to amount of moisture already in the gravel. The water is thoroughly worked in until the mixture has the consistency of mortar. Only a small amount of sand in the gravel is needed, gravel about the size of eggs being most economical. *Mix thoroughly, and when using ram down hard.* It is better to excavate to get a good foundation. The foundations for walls are usually eighteen inches thick, and on this is built a ten-inch wall, the wall being built in center of the footing (foundation.) This size wall will support any weight in connection with a barn structure. Planks and studding are used to hold cement concrete while building; another method is by the use of clamps. A railroad barrow is the most useful article for carrying the concrete mixture around in. Large stones can be used in the heart of the wall, but they must be rammed down tightly. One barrel of cement will, with the necessary gravel, build a wall thirty-five feet long and one foot high. Good cisterns can be built in the ground with this material. The walls are usually four inches thick, with a parachute roof—eighteen to twenty-four inches of a rise. In this roof is a manhole twenty inches across. The manhole trap is of iron.

CONSTUCTION OF FLOORS.

The manure trough (gutter) is put in first, then a 2×6 on the floor side and 2×8 stall side is used to hold the cement in place. There is a slight slope in the stalls, about three-fourths of an inch. The floor for a cow stable is made about three and one-fourth inches thick, two and one-half inches of the rough, six to one concrete, being used and rammed down thoroughly, then about three-fourths of an inch of the two to one concrete being used on top of the first lot. In this method one barrel will put in about fifty square feet. A floor is all the stronger and will wear better if it is three-fourths to one inch thicker with the rough concrete, six to one. The foundation for the floor should not be broken stones, as they let air in and the concrete will dry out too quickly It is far better to level the earth thoroughly, then put on a layer of sand or gravel one to two inches thick—on top of this the concrete. Never put the concrete right on clay. Sockets are made 6×6 and built in at the side for the stall posts. The sockets are made by using watersoaked blocks 6×6, which are left in one-half to one hour, then withdrawn, and a hole is left in which the stall post is placed. In horse stalls a two inch fall is given. If sharp-shod horses are stabled, the floors should be planked on top of the concrete. Floors should not be polished with an iron towel, as it will make a slippery floor.

Note.—The bottomless box used for mixing the concrete in, has cleats nailed along each side, to be used as handles to lift it around by.—*Farmers' Advocate.*

The Season for Fattening Hogs.

In his "Pork Production," F. D. Coburn, Secretary of the Kansas State Board of Agriculture, has the following to say on the above subject:

There are two seasons of the year, when the greatest gains can be made in hogs of the same type, and under similar conditions with the same amount of corn. These are early in the spring, before the weather becomes excessively hot, and in September, October and November, before it becomes excessively cold. Prudent farmers, therefore, aim to do the bulk of their feeding in these months. The objection to early fall feeding, lies in this, that the packers usually make a combined effort to beat down the price of hogs at the beginning of the packing season. The fact that a very large per cent of the hogs are fed in the fall of the year, and thrown upon the market, enables them to do so in ordinary seasons without much difficulty. This season, however, is likely to prove an exception. The packing season begins the first of November and the sharp demand at present prices, for both live hogs and pork products, makes it probable that the usual effort will not be made, or at least, not with the earnestness this year. While it is true, as a rule, that higher prices prevail in February and March than November and December, the difficulty in making weights during the first named months, and the heavy expense involved in the way of keeping up the animal heat, go far to neutralize the difference in prices. Where the farmer does not sell in car load lots, it is a good thing to have a few hogs to turn off at different seasons of the year. It is also a good plan to have the largest lots to turn off at the close of the season, when the greatest gains can be made with the same amount of corn. Much of the loss in hog feeding, in extremely cold weather, can be avoided by securing proper shelter. Corn must be very cheap indeed, if it is not dearer than pine boards at present prices. It must be understood, that the food that is used to maintain animal heat is just as truly used as fuel in the hog, as coal is used in the stove for maintaining the temperature of the home. The warmer the house provided, ventilation and other health requisites being secured, the less fuel is required. The same rule applies in the hog pen. Heat may be purchased at too great an expense to health at the home, as well as in the pen. The permanency of prices requires that marketing of hogs should be kept up over the entire year. The market necessitates feeding, and while it is true that the greatest gains can be made at the seasons above mentioned, and while it is also true that it is usually more convenient to feed a large number in the fall of the year, for obvious reasons, yet the farmer should be prepared to feed off hogs at any time, and at the weights which the market requires.

Kansas Cows.

The total number of milch cows in the state is 684,182, an increase of 78,257, or 12.9 per cent. Dickinson county leads with 14,948, with Pottawatomie, Osage, Sedwick and Washington following in the order named; the aggregate gained of these five counties is 7,716. The increase in milch cows in 1897 was 37,463 and in 1898, 53,387, making a total increase for the three years of 169,107.

The number of cattle other than cows is the largest Kansas has ever had, and for the first time in the history of the state, has passed the 2,000,000-mark; in the last four years the number has increased nearly 1,000,000 or 75 per cent. This year's gain over 1898 is 203,746, or 10.19 per cent, making a total of 2,201,886. Greenwood county retains her lead in other cattle, having 69,177, followed by Barber with 65,806, Butler 59,610 and Cowley 56,829.

CONCERNING OUR ADVERTISERS.

THE following letter just received from Henry Stevens & Son, indicates that Holsteins are as usual, in brisk demand:

ED. HOARD'S DAIRYMAN:—Among recent sales from Brookside were three beautiful two-year-old heifers to that extensive and well known breeder, Mr. A. A. Cortelyou, Neshanic Station, N. J. These heifers were not only fine individuals, but exceptionally well bred and all had made large official butter records.

Mr. W. A. Matteson, Utica, N. Y., Pres. of the H. F. Assn., also purchased of us two very fine show animals.

We have also shipped to Mr. B. F. Wright, North Ridge, N. Y., the fine yearling bull Duchess Ormsby Prince. His dam, Dutchess Ormsby 3d, was very sucessful last season as a two-year-old in the show ring and is also a very large producer. She won first prize in the two-year-old class in the seven day butter contest at the Omaha Exposition last fall.

Our sales of young bulls have been good but we still have on hand thirty bulls from two months to ten months old, many of them are backed by the largest official butter tests ever made.

Feed in pastures has been good until recently and our cattle have done exceptionally well; our herd now numbers 160 head. We are building a silo and extensively repairing the barns on a farm we purchased last winter, and are not going to be able to show this fall, but are glad to know that our breed will be well represented at most of the leading fairs and we feel confident that they will continue to take the lion's share of the prizes in competitive butter and milk tests.

Lacona, N. Y. HENRY STEVENS & SONS.

We wish to direct the attention of our readers to the advertisement of the Janney Mfg. Co., of Ottumwa, Iowa, which makes its first appearance in this issue. As the reader will observe these people are the manufacturers of the famous corn husker and fodder shredder bearing the firm's name. We are assured by the manufacturers that this machine is no longer an experiment but an assured success. This fact is borne out by the excellent line of testimonials set forth in their published matter. It would seem to us that this machine should prove a boon to farmers, in that it saves entirely the element of hand labor which now enters so largely into the expense of growing a corn crop. Anything which will save that expense will certainly tend to increase the profit of growing a corn crop. Write these people for circulars, etc.

VERY POPULAR.

The "Osgood" Standard Scales, manufactured by the Osgood Scale Co., Central Street, Binghampton, N. Y., are the subjects of an illustrated announcement to the trade, in this issue. They emphasize the fact that they want dealers and agents everywhere to handle the farm scale. The house adds a proposition to ship scales on a thirty days' trial. The wagon scales made by this firm are becoming very popular, and the sales are larger than was expected. A catalogue will be sent on application.

CLEANLINESS and comfort of the domestic animals are to be provided in every form available. The dairy will be in every sense more attractive if the owners of cows will use the Newton Cow Tie, an illustration of which will be seen in their announcement in our columns. For further particulars our readers should address the E. C. Newton Co., Batavia, Ill.

Horse Owners! Use

GOMBAULT'S

Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from **Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING.** *Impossible to produce scar or blemish.*

For Cows and Calves.

A Specially Constructed Hollow Bit to Prevent Cows and Calves from Drawing Milk.

Will be sent postpaid for **50 CENTS.**

Will be sent as a premium for

ONE NEW SUBSCRIBER.

A MILK dealer in Madison, Wisconsin, who was arrested and fined for using preservatives in his milk, explained its use as follows:

Mr. Wergin explains the manner in which he, unknowingly, violated the law by the statement that the preservative used was purchased from a Chicago firm, whose agent stated that it was the same thing as is used in pasteurizing milk and cream, which is permitted under the law.

Here is a good illustration of how expensive ignorance is. A little reading would have shown the difference between the "preservatives" and pasteurization, and saved $25.00 fine and the loss of customers, which usually follows such a conviction.

Good Results From the Plowing Under of Green Clover.

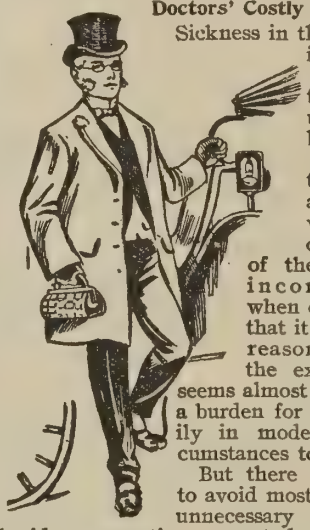
Among the many things of interest seen by the large number of farmers who have visited the Central Experimental Farm at Ottawa, during the past few weeks, none have awakened greater surprise than the striking illustrations made this season showing the advantage to crops of the plowing under of green clover. This is particularly seen in a field of oats of about ten acres. This land in its preparation in the spring, was treated the same throughout; the field was all sown the same day with one variety of oats, the Bavarian. Last autumn about eight acres of this field had a good mat of red clover turned under, which was grown from seed sown (ten lbs. per acre) with a barley crop in the spring. One acre was plowed which had been in Brome grass for two years. One acre, which had been occupied with other pasture grasses for a similar period; and one acre with a mixture of pasture grasses and clover.

Over the whole area where the clover was turned under, the increase in the growth of the oat crop is most striking. The difference in the highest part of the grain will average about twenty inches, and the deep green color of the leaves on this part of the field and the vigor of the plants are in striking contrast to the crop on the adjoining land, where there was no clover. This remarkable increase in growth, affords convincing proof of the added fertility given to the land by the plowing under of green clover. In another field, which has been planted with potatoes, a strip of the land covering eight rows of this crop had clover grown on it last year, which was plowed under. In that strip the growth of the potatoes, as compared with the same variety on the adjoining land where there had been no clover, was quite remarkable, the plants being much larger and more vigorous. The results of the crops in both those instances will be watched with interest.

Last year a like illustration was given on eight plots of land on another part of the farm, on four of which red clover had been sown with grain in the spring of 1897; while on the other four, grain was sown without clover. This land was all plowed in the autumn of 1897 and in the spring of 1898 the whole area was sown with Banner oats. The greater vigor in the growth of the grain where the clover had been turned under, was very noticeable quite early in the season and became more striking as growth advanced. These results were brought under the notice of a large number of visiting farmers during the season of 1898. When this crop matured the grain on these eight plots was harvested and threshed separately and the yield per acre on the four plots on which the clover had been grown, exceeded that obtained from the plots on which there was no clover, by an average of eleven bushels and one pound per acre.

In another field clover was similarly sown, in 1897, in different quantities with grain on a series of plots with three left as check plots without clover. As these were all to be planted with Indian corn they were not plowed until May 23rd, 1898, by which time the clover had made a heavy growth. After plowing and harrowing, the corn was planted, and when harvested in the autumn the average crop on all the plots on which not less than eight pounds of red clover had been sown and plowed under, exceeded in weight the average yield of the three check plots on which there was no clover, by four tons, two hundred and thirty-three pounds per acre.—WM. SAUNDERS, Director Experimental Farms, Ottawa, Ont., in *Farming*.

The Sand Vetch.



Among the various leguminous crops recently introduced into this country, with such manifest advantage to the farms and farmers, there is not one which, in our judgment, promises greater results than the sand vetch, or hairy vetch as it is sometimes called; and especially is this so in the South, where our greatest need is something to cover up the land, and continue growth during winter, and thus prevent the leaching and wasting of our soils by the rains. German or crimson clover is a most valuable plant for this purpose, but, unfortunately, it is easily killed by drouth or the hot sun in the early fall months, when just germinating, and the securing of a stand has been found to be a great difficulty in the way of its adoption, with any degree of universality. In many sections it is largely grown, and its value as a forage crop and as an improver, is so great that no effort should be spared to secure, at least, a few acres, by making several sowings at intervals during this month and the next. The sand vetch has come to us as a valuable adjunct to this clover. For the past three or four years it has been tested widely throughout the country, and very fully in Virginia. It has been found to be perfectly hardy and not nearly so susceptible to killing by the hot sun or drouth in the early fall, as crimson clover. Whilst it does not make a very vigorous growth during the winter, it yet lives and grows, and is ready to push into quick and luxuriant growth as soon as ever the mild days of spring set in. When once this growth starts, it continues through wet and drouth, and the quantity of forage made is wonderful. It has made as high as 45,000 pounds of green feed to the acre, and this feed is of the most nutritious character. It is much richer in protein (the muscle and growth producing element) than red clover, or than the cow pea, whilst in fat-producing matter it is nearly the equal of those plants. As a soil improver it is richer in nitrogen, phosphoric acid and potash than any of the clovers or the cow pea. If intended for forage or hay, it should be sown at the rate of thirty or forty pounds to the acre, with a light seeding of winter oats, wheat or rye. This will hold up the vines, and make it easier to cut and harvest the crop. If only intended as a pasture or an improver, sow alone at the rate of forty or fifty pounds to the acre. Sow in August, September or October, on well prepared land. When sown alone it will make a perfect mat all over the field, which will continue to increase in thickness all through the spring and summer, as the vines fall down and grow through again. One of our subscribers had a large field of this vetch last year, which was sown alone, and intended only as an improver of the land, which in the early fall was covered with a mat of the vines, six inches thick, and so dense that not a particle of soil could be seen. When plowed down the soil was found to be as mellow and full of vegetable matter as possible, and when consolidated with the roller was in the finest condition for the production of wheat, winter oats or grass crop.—*Southern Planter*.

Skim Milk as Human Food.

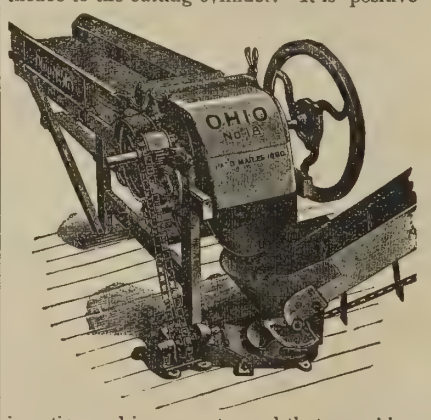
Skim milk contains nearly all of the food value of the original milk, with the exception of the fat, and even this may be present to the extent of from one-tenth to one per cent. It contains from three and five-tenths to four per cent of protein, about five per cent of milk sugar and eight-tenths per cent of ash or mineral matter. Its chief value is as a muscle-making food, and hence it is of great value to growing children or laboring people. Its economy as an article of diet can best be shown by comparing it with other foods. Twenty-five cents will purchase six and one-half times as much total nutrients and five times as much protein in skim milk at two cents a quart, as in sirloin steak at twenty-two cents, or four times as much nutrients and three and one-half times as much protein as mutton shoulder at fifteen cents a pound. Or three quarts of whole milk, worth from six to eight cents at retail, will hold more total nutrients and more protein than a pound of round steak. At the present prices the only common food materials that will furnish more protein for a given sum of money than skim milk, are beans, wheat, flour, oat meal, corn meal and salt codfish.—Prof. C. S. PHELPS, in *Homestead*.

Doctors' Costly Visits.

Sickness in the family is hard enough to bear under the best of conditions. It almost always cuts off part of the regular income, and when on top of that it adds unreasonably to the expense it seems almost too great a burden for any family in moderate circumstances to endure.

But there is a way to avoid most of these unnecessary expenses besides preventing a great deal of the sickness itself.

"Doctor's visits come high," says Mrs. Bela F. Howard, of Glen Ellen, Sonoma Co., Cal. "I have been in this place sixteen years and have only had a doctor once in my family since that time, thanks to Dr. Pierce's Common Sense Medical Adviser and his medicines. This book saves doctor's visits. I cannot do without it in the house. I have had two copies but cannot keep them. Enclosed I send 21 one-cent stamps for another copy." Another lady, Mrs. Jennie Warren, of Clifton, Graham Co., Arizona, says: "With pleasure I write to you again to let you know that I feel as well and strong as I ever did. With your kind and good advice and Dr. Pierce's Favorite Prescription I have been entirely cured. I thank you a thousand times for your good advice. I think that if every person who is sick in any way will write to you for advice and will take the medicine you prescribe, according to directions, no other doctor's services will be needed."



The great thousand-page Medical Adviser will be sent free paper-bound for 21 one-cent stamps to pay the cost of mailing only; or in cloth-binding 31 stamps. A whole medical library in one volume. Address R. V. Pierce, M. D., Buffalo, N. Y. He will send professional advice (in a plain sealed envelope) free of charge. All letters are considered in sacred privacy, and never published except by the writer's permission.

ILLUSTRATION.

SOMETHING NEW IN FEED AND ENSILAGE CUTTERS.

We are presenting herewith, for the benefit of our readers, something entirely new in the way of an ensilage and feed cutter. This is one of the "Ohio's" which are so well and favorably known to our readers and to the public in general. This new machine is styled the "Ohio" Standard Self Feed Ensilage Cutter. It differs from the regular "Ohio" line of cutters in the following essentials:

This machine is equipped with a direct and positive self-feeding device termed a traveling feed table, which consists of a web of hard wood slats passing over sprocket wheels, and delivering all fodder immediately to and between the feed rolls, and thence to the cutting cylinder. It is positive

in action and is so constructed that anything thrown upon the web or moving table must be passed on to the knives. Conveniently placed levers enable the operator to control the feed perfectly, however, stopping and starting instantly, should that be necessary, without skip or jar and without breakage, making the machine absolutely safe, and preventing the introduction of any foreign substance which might injure or break the knives or machine.

The greatest advantage in this new feed table, however, is the ability to increase the capacity of the machine, and at the same time save labor.

The new Metal Strip Swivel Elevator is another vast improvement applied to the "Ohio" machines. It will be observed that by a pivotal attachment this new feed carrier or elevator may be instantly adjusted to any direction and lowered or raised to any desired angle. A great advantage and the saving of much time is found in the fact that it is not necessary to take off the elevator chain in setting up, or otherwise changing the machine. The metal buckets used on this elevator to take the place of the old-style wood slats are made to correspond to the greatly increased capacity noted above, and easily take care of and deliver all feed passing through the machine. In all other respects this machine is the exact counterpart of the famous "Ohio" cutters, all of which are manufactured by the Silver Mfg. Co., of Salem, Ohio. They will take pleasure in mailing you a more complete description of their Ensilage and Fodder Cutting Machinery.

Winter Crops

perish when they lack nourishment. Liberal fertilization insures the vigor necessary to resist winter killing.

Potash

Phosphoric Acid and Nitrogen in well-balanced proportions, are what they need.

Send for our books telling all about composition of fertilizers best adapted for all crops. They cost you nothing.

GENESEE SALT

for five years in succession to win the SWEEPSTAKES PREMIUM of the NATIONAL CREAMERY BUTTERMAKERS ASSOCIATION? Certainly they were good buttermakers, but perhaps the Salt had some little to do with the result. The winners were as follows:

In 1895.....F. G. OLTROGGE
In 1896.....THOS. MILTON
In 1897.....H. N. MILLER
In 1898.....S. HAUGDAHL
In 1899.....R. T. MCCOLL

Study your own interests, use **GENESEE SALT,** and write to our General Western Salesman, Mr. F. A. TRIPP, 34 Clark Street, Chicago. Or address

Yours truly,

THE GENESEE SALT COMPANY, New York.

THE NEW BOOK
Feeds and Feeding

By Prof. W. A. HENRY,

Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

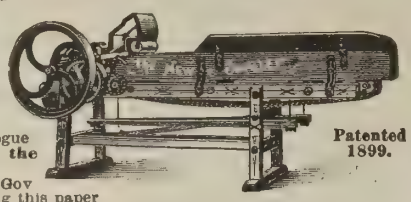
Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library. and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.



Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

MAKE ONLY SWEET ENSILAGE

Ever since the ensilage system has been introduced in this country it has been the ambition and effort of siloists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste.

The best way to Shred Ensilage is with the

St. Albans Ensilage and Fodder Shredder.

It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail free a pamphlet on the subject.

Attention Dairymen!

THE LARGEST PREMIUMS ever offered for Dairy Products in the state is now provided in the dairy department of the **WISCONSIN STATE FAIR,** to be held at **Milwaukee, Sept. 11, 12, 13, 14 and 15, 1899.** Every creamery, dairy, or cheese factory in the state should make an exhibit. Remember if you do not win the Sweepstakes Prize you are sure of your share of the pro rata premiums, which for butter amounts to over $360, and for cheese $330, besides Special, and that duplicate score cards with all special defects, if any, written thereon, will be mailed to each exhibitor in a sealed envelope. Now is the time to make the dairy department of the State Fair what it should be—second to none. Wisconsin Dairy School Students are especially invited to exhibit samples of their dairy products. All exhibits will be carefully looked after and taken direct from the Express Wagon to the large glass Refrigerator in which it will be exhibited. Special attention will be given to re-shipment or selling exhibits at close of fair according to directions received; this will be under the personal supervision of Prof. E. H. Farrington, of the Dairy School. All articles, after being receipted for, will be taken direct from the refrigerator by the Express Co. Exhibitors should write their name and P. O. address plainly on bottom of each package.

All manufacturers or dealers in dairy supplies are specially invited to exhibit. At the Fair is where you will find the wide-awake, progressive and enterprising dairymen, and these are the men you want to show your goods to.

Address all communications in regard to Entries to **JOHN M. TRUE, Sec'y, Madison, Wis.**

IT DOES NOT Create an Oder to Destroy One.

SAN FRANCISCO, Sept. 22d, 1896.
I have used "Purifine" in cleansing milk cans and bottles and find it will remove the bad oder left by old sour milk more effectually than anything I ever tried.
E. A. GREEN. Sec'y,
Millbrae Dairy Company, Mission & 9th.

Applied with large quantity of water, which makes it **cheap and convenient of use.** It is invaluable to the cleanly dairyman or factory operator. Once try, you'll never be without.
SEND $1.00 FOR SAMPLE GALLON by Freight.
This powerful disinfectant creates no odor of its own, but will keep creamery, cheese factory and dairy pure and sweet. TRY IT ONCE.
FITCH CHEMICAL COMPANY, Bay City, Michigan.

A Business Talk.

The great majority of creamerymen this season will buy some new material for their creameries. It is important that this material shall be of good quality. It will last longer and be cheaper in the end than the average of such supplies on the market. When

FITTING UP A CREAMERY

See that the **Vats, Churns, Butter Workers, Tin Ware, Butter Boxes, Engines and Boilers** are of the Haney-Campbell manufacture. They cost no more than the other kind, but are of much better quality. Mere mention of these things is meaningless; they must be seen to be appreciated; they must be tried to appreciate their excellent lasting qualities.

Tubular Separators have conquered the world in the matter of clean skimming. They produce a smooth even cream, and have large capacity. They run without the use of a steam engine and have practically no wearing parts.

Babcock Testers are machines that have been made on clap-trap lines until recently. We have a full line of the Elgin Manufacturing Co.'s testers—**No-Tin, Russian** and **Standard.** Send for our illustrated catalogue.

HANEY-CAMPBELL CO., Dubuque, Iowa.

DAIRY AND STOCK FARMERS Will do well to inquire about the fine meadows in Aitkin county, Minnesota, where splendid stock lands can be bought for $3.00 to $5.00 per acre on 10 years time at 6 per cent interest. Cheap railroad rates whether you buy or not. For maps, rates and further particulars write L. B. ARNOLD, Agent, 901-5 Guaranty Building, Minneapolis, Minn.

Convince Yourself.

Does it ever occur to you that a practical demonstration of merit is worth more than the "tale of woe" which comes from a salesman with an "ax to grind." It is remarkable how wonderfully interested in the welfare of the creamerymen (?) some wild eyed competitors of the Tubular have become. Why are they so energetic in their efforts to prevent creamerymen from giving the Tubular a trial? Because they are trembling in their boots. Do they fear that the creameryman will be the loser? Oh, no! Because it is the last card they have to play, and they know that when the Tubular is given a fair trial it gives satisfaction and proves itself in every way superior to their back number machines. Some of these fellows have been weeping "crocodile tears" over Mr. J. A. Chillqvist, of Nettle Creek, Ill., but the following letter from this gentleman shows that it has paid him to use his own judgment rather than listen to false friends.

NETTLE CREEK, ILL., August 4, 1899.
The Sharples Co, Chicago, Ill.

Gentlemen:—Your letter of inquiry of a recent date was duly received and should have be answered sooner but from the fact that I wished to see fully what the Tubular would do. I have now fully decided after carefully testing the machine, and am prepared to say that it meets fully your recommendation, and even more, as it requires very little power to operate same and the cream is equal, and I believe superior, to any separator that I have ever used. I have used separators for the last fifteen years, including nearly all makes, Danish-Weston was the first, then De Laval and Sharples and also Alpha, all of which I considered good, but I now say from experience that I regard the Tubular separator as the leading machine. I was warned against using or buying this as it was an experiment; it has proved to me the right kind of an experiment. What can we expect unless we look to advancement. I am skimming 2500 pounds per hour and this not to exceed .03 to .05 and have always found that my own judgment has served me better than the talk of competitor's agents of separators or anything else. There are several Tubulars running near me, and all are more than pleased with results from their machines. Yours truly,
C. A. CHILLQVIST.

The Sharples Tubular Separator

Represents the latest great advance in cream separator construction. More revolutions, less speed, more centrifugal force, less power, more perfect cream, less fat in skim milk, more durability and less complication.

The Bowl alone Revolves. It is a Hollow Bowl. It Spins on Air. Placed on Trial and Results Guaranteed.

EXPERT TESTIMONY

SUBJECT:

Disbrow Combined Churn and Butter Worker

Witness: A. M. LARSON, Meriden, Kan.

MERIDEN, Kan., August 6, 1899.

T. J. HOWE, Esq, Owatonna, Minn.

Dear Sir:—Yours of the 1st inst. to hand, and in reply will say, that I have used a Disbrow No. 6 for about a year and a half and it has worked to my entire satisfaction. The churn is very light running and the engineer says, "it takes only about one-half the power it did to run the 400 gallon box churn which we had in before we got the Disbrow." While we had the box churn we could hardly churn while the separators were running, as it would shake them and make them tremble so it was hardly safe to be in the room where they were We experienced nothing of that kind since we got the Disbrow; it runs steady and causes no vibration, the gearing is very simple and is changed from churn to worker and reverse.

I have less trouble with mottles since I have used the "Disbrow." When the butter is taken out of a box churn to be worked, the temperature, either warm or cool, the surface of the butter, as it is hard in an average creamery to have the temperature the same as the butter, the soft part gets worked or overworked before the hard butter gets worked, and the result is badly mottled butter. The combined churn and worker keeps the butter at an even temperature, and consequently less mottles.

I always revolve the churn twice, in slow gear, after I have salted the butter and before I change it to a worker. To revolve the churn in fast gear is very hard on the churn and should never be done at the above stated time, but when put in slow gear the churn revolves as smooth as if there was no butter in it, and the revolving of the churn two to three times after salt is added before changed to worker, incorporates the salt with the butter.

I have churned 1,000 lbs. at one time in the No. 6, but think it a little too much; 900 lbs. is about right. I do not think it is worth the while touching upon the work that is saved by using the combined churn and worker, as I think it saves the buttermaker half the labor there is in using a box churn.

Trusting that my information is what you want, if there should be anything I have not touched upon, will be pleased to give you the information I can.

Respectfully yours,
A. M. LARSON, Buttermaker.

THE DAIRY "VICTOR" Churn.

This Combined Churn and Butter Worker is proving itself to be precisely what the farmers and dairymen have been seeking after. It's work is as complete as the work of the "Factory" Victor Churn, which is rapidly supplanting every other Combined Churn and Butter Worker.

IT IS THE ONLY SUCCESSFUL DAIRY COMBINED CHURN AND BUTTER WORKER ON THE MARKET.

It is easy to handle, easy to clean, perfect in its work, durable and reliable. It charms every farmer and dairyman who sees it work. Manufactured by . . .

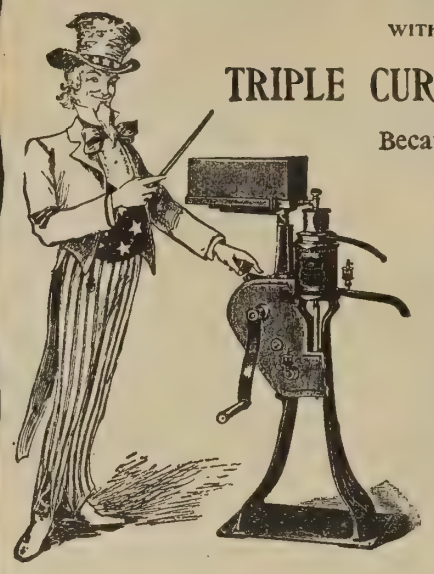
F. B. FARGO & CO., Lake Mills, Wis.

Be Fair with Your Fields

and they will be fair with you..... Listen a moment.

Every time you take a crop off a field you relieve it of just so much fertility. You should do something to restore that fertility. Barn yard manure is the best fertility restorative known if properly handled and properly applied. Even a small amount can be made to go a long way and accomplish great good if finely and evenly spread. This cannot be successfully done by hand—it is work for a perfected machine. The only machine known which accomplishes this is

The KEMP MANURE SPREADER.



It will Double and Treble the Value of the Manure Heap.

It spreads all kinds of **fine and coarse manure evenly;** it makes no "skips;" does not dump a great load in one spot, but covers the entire ground evenly. Tears up coarse and lumpy manure and makes it fine. Better than anybody can do it by hand. **Spreads lime, wood ashes, salt, etc.,** equally well. With the drill attachment **it puts the manure direct into the open drill.** Made in three convenient sizes. Ask the opinion of anybody that uses one. **Write for illustrated catalogue.**

Reading notices, 50 cents per line (nonpariel measure) each insertion.

WALTER O. CLARK, of Des Moines, Iowa, sued Edward Dicks in the District Court and obtained a verdict for $855 for damages to his health, resulting from the use of a tuberculous cow, which Clark had rented of Dicks. Clark's physician testified that he, Clark, had been greatly injured by the use of the milk of this cow. It is somewhat difficult to see how the doctor could testify that he knew Clark had acquired tuberculosis from the cow and from no other source.

LAWS REGARDING OLEOMARGARINE.

The decision of the Maryland Supreme Court, in a recent oleomargarine case, appears to us to be a strained effort in behalf of the counterfeit, and against the honest product of the farm. But the farmers of Maryland must not become discouraged.

No judge or court has long maintained itself, that was seen to be without sympathy for the products of honest toil, and in favor of a counterfeit that depended on deception and fraud for its sale and success.

The recent decisions of the United States Supreme Court block out the limits of constitutional legislation very closely, which may be defined as follows:

"State laws prohibiting coloring oleo to resemble butter are valid, but state laws forbidding oleo in its pure uncolored state to be brought in are not valid, neither are state laws requiring oleo to be colored any particular color.

State laws prohibiting the sale of oleo inside of a state from one citizen to another are valid, provided the seller is not the importer.

State laws prohibiting the manufacture, sale or importation into a state of oleo, made in the semblance of butter are valid.

The smallest package of oleo that can be originally put into a package is ten pounds, and no dealer is allowed to sell a package of oleo, in excess of ten pounds, unless he holds a license as a wholesale dealer."

SOME HOLSTEIN ILLUSTRATIONS AND RECORDS.

We give on this page a couple of illustrations of cows from the herd of W. B. Smith & Son, of Columbus, Ohio, and invite attention to the communication of Mr. C. G. Williams, in another column, describing the herd and the manner by which it was built up.

There is something more than a merely casual correspondence be ween the "style" of these cows and the records which follow their pictures. A slight rearrangement of the letters,—simply transposing the s and the u, which makes the word read "causal"—describes and explains this correspondence.

We place but little reliance on the numberless "signs" which are put forth from time to time as the infallible indications of dairy ability, unless they can be shown to rest upon some sound physiological basis, and contribute in some way to the adaptation of the animal to its environment and the work required.

PANA 33959, H. F. H. B.

Born Aug, 5, 1892. Dropped last calf Feb. 20, 1899.

The total yield for the seven days, March 19–25, was 539.6875 lbs. milk containing 15.5281 lbs. fat; equivalent to 19.41021 lbs. butter, containing 80 per cent fat.

We demand the arching flank and the thin, incurving thighs, because without these there will not be adequate room for a useful udder; we want a rising pelvic arch—about which the *Jersey Bulletin* makes itself almost irresistibly funny—because it indicates that nature has thereby provided the best possible kind of framework for supporting extra weight. We do not expect to draw milk from "thighs" or "pelvic arches," but when we see the provident mother of the old time, knitting woolen socks and mittens in July and August, in anticipation of the demand that will come in January, and the modern mother providing in other ways for the future wants of her household, we feel well assured that nature, not less provident, works on well defined and harmonious plans. When, therefore, we see the combination of incurving, thin thighs with a well cut up flank, we have reason to expect that in due time and with proper care, there will be an udder to occupy the space. If, in addition to this, there is a rising pelvic arch, we may conclude further that there has been wise provision for carrying this udder without undue tension upon the spinal column.

But the most perfect machinery in the world is worthless without power to run it. It is of little avail that a cow has adequate provision for an udder, unless there is also the means for supplying that udder with the necessary material for it to work upon. This must come from the food eaten and digested. The model cow must therefore have large storage and digestive capacity.

Observation has also taught us that milk making is intimately connected with, and dependent upon nerve force. The good milch cow has abundant nervous energy, which is largely supplied by the nerves radiating from the spinal column. It is immaterial that we cannot trace out and explain all the whys and wherefores of the mysterious connection of the nerves with the elaboration of milk. Possibly some day there will develop a physiologist of sufficient keenness of perception to discover these things, but for the present, we must be content to accept the fact, and draw the conclusion, that in some way a large backbone, with its processes not too closely interlocked, contributes somewhat to the efficiency of the cow as a milk producer.

PAYNE'S LADY DEVRIES OF ROCHESTER 2nd, 32883 H. F. H. B.

Born April 23, 1892. Last calf May 4, 1899.

The total yield for the seven days, May 17–23, was 570.25 lbs. milk, containing 17.06 lbs. fat; equivalent to 21.375 lbs. 80 per cent butter.

There are those who talk or write, with considerable appearance of great learning, about the necessity of heart girth and lung room. We have to say in regard to such matters that it has never yet been shown that any cow was ever deficient in these respects. Mere outside appearances and measurements are not indicative of the size of the internal cavities. Wherefore, other points being satisfactory, we may not be seriously alarmed if the animal is not over wide between the forelegs, and does not girt up to somebody's arbitrary standard.

It seems to us that the foregoing is a fair statement of what one would expect to find in a good dairy cow. If he was about to have one built to order, these are the main points to be insisted upon. The illustrations on this page give us from life, without any addition or pruning, the outlines and general form of two cows who have demonstrated their right to be classed as good cows. Do not the theories and the facts correspond? Is it not demonstrated that there is such a causal relation between form and performance, that, either one being given, it is not impossible to predict with some approach to exactness what the other will be.

We cannot conclude these hastily written notes, without renewing our protest against the custom of our Holstein friends estimating the yield of butter, by adding twenty-five per cent to the total amount of fat. This was not, as they seem to claim, the rule at the World's Fair. As a matter of fact the churned and well-worked butter there, showed an increase of only about 16⅔ per cent, and when this butter was reduced to the eighty per cent of fat standard, the increase was less than twenty per cent.

How the Hollanders Do.

In speaking of the necessity for the dairyman who wants good cows, to raise them, and further that he shall use wise dairy methods in doing the same, an eastern exchange says:

"It may not be amiss on this point to call the attention of our readers to the method adopted to the Hollanders, who are dairy farmers by instinct, and whose ancestors have followed the business for hundreds of years. In order to keep their dairy cattle up to the standard, they in the first place select the bulls invariably from the calves of their choicest milkers. In like manner they sell all their heifer calves for veal, or as yearlings, except about twenty per cent, and these are selected from their choicest milkers and raised on skim milk and other feeds adapted for growth instead of for beef production. In addition to this, they apply the greatest of all tests, performance at the pail. These heifer calves are brought in at about two years old, are thoroughly tested as to milk production, and if they do not prove satisfactory are sold for beef after their first season.

This is a rational way of procuring a herd of best milking cows. In fact, it is the only way, and if any of our readers wish to have a herd of ten or twenty cows that will give them between two and three hundred pounds of butter fat a year, they must select the sire from deep milking strains of whatever breed they have, must select the best heifer calves from the best milking cows, must feed these heifers for growth and not for beef, on oats as a grain feed instead of corn, and then reject the unworthy ones."

Feeding for Eggs.

It is difficult to give a general formula that will suit all conditions, still we believe in the morning mash, winter and summer. It is composed of one-half ground corn and oats, one-fourth bran, and one-fourth boiled vegetables or soaked beef scraps, or cut clover hay steamed; mixed with boiling water at night, covered up and left to steam and fed warm in winter. In summer, cold water is better. Whether to feed this mash every day or every other day, (alternating with wheat, or wheat and cracked corn mixed in winter) can be decided by experiment. Meat in some form, either raw or cooked, should be fed two or three times a week, and green food every day, winter and summer, if fowls are confined in yards. Green cut bone is an excellent feed, either separately or mixed with the mash.

Our manner of feeding for eggs is to give the mash every other morning in summer and every morning in late fall and winter. Care should be taken, however, not to give a full meal, but sufficient to satisfy hunger, and thus compel the hens to hunt around for whatever they may find in the yards or litter of the crops. We feed nothing at midday but green food, such as cabbage, and at night, wheat, oats and cracked corn, separately or mixed together. The heavy breeds being generally less active than the light, need to be carefully fed and kept busy scratching. Avoid over-feeding if you wish an abundance of eggs.—*Country Gentleman.*

A DES MOINES daily paper says that the pasteurization of milk consists in separating the fat from the milk and then remixing it in different proportions, suited to the needs of each particular baby. What the average daily paper don't know isn't worth knowing!

HOW SHE WAS BRED.

When a ship is to be built the first thing they do is to employ a designer to draft her lines. If, after she is built, she does not sail well the blame is laid to the designer, and it is usually a right judgment. The principles of intelligent dairying apply in the same way to the construction of the modern dairy cow. Here is a chance to use fine skill and judgment, a chance to be broadly intelligent, a chance to take hold of and use the rich treasures of other men's experience and wisdom. When the cow is launched, if she does not sail well, if she refuses to keep up with her companions and make profitable voyages each year for her owner, it is comparatively easy in looking her over to note whether she was well constructed along the lines of the best dairy performance. If she was not, it will show in her "lines" as the ship builders say. Faulty lines make faulty performance. Is it not so in nearly everything?

A sewing machine must be built along the lines of its performance or it will not perform well, any more than a ship. So must a mowing machine, or any other machine be built. Every time, it is the work they have to do that must govern in their construction. The same principle holds good in all other domestic animals, and in the birds of the air. A greyhound is designed for great speed in running, and he is built that way; a bull dog is built for fighting and his build shows it. A game cock is designed for fighting in another way. See how trim and muscular he is built, designed for the greatest activity, courage and gameness possible; not an ounce of superfluous flesh on him.

So it is with the dairy cow, and if the farmer has vague and wrong notions as to her form and build it will tell every time in her appearance and the outcome of her performance. A. M. Stevens, of Washington, bred the grade cow Peggy of Elmwood. He took a native cow of decided dairy form. This cow he bred to a three-quarter Jersey bull. A heifer calf was the result, the mother of Peggy. Then he bred the mother back to her own sire, and the result was Peggy. In a test at the state fair Peggy was put on the course and tested in company with four other cows. The test was reported in the DAIRYMAN of Oct. 28, last year. The test was for two days. In this time she gave forty-nine pounds and ten ounces of milk a day, testing 4.32 per cent, equivalent to two pounds and fifteen ounces of butter a day. Note well that she was not only a dairy cow, but still more, was bred in a dairy manner and fashion. Care was taken that from the bottom up, her lines should be laid in a specific dairy style. As a result she answered back in strong response to the dairy skill and judgment of the man that bred her. There is meat in this experience, for all men to take and consider who would learn well how to design and construct a profitable cow. The principle involved applies equally well to all dairy breeds.

OLEOMARGARINE AS BUTTER.

There are, in the aggregate, a large number of people who, never having come in personal contact with oleomargarine or its promoters, are disposed to believe that the crusade against it is prompted solely by personal motives, and in the interests exclusively of dairymen. They look upon the subject as merely a contest for supremacy in the market between two rival food products of practically equal merit. They take for granted that the inspired (?) articles in the metropolitan newspapers, praising the product of the slaughter house, and the certificates given by expert (?) chemists as to its healthfulness—both of which are on an equality with much of the testimony in the Dreyfus case—are statements of facts. They will not knowingly use oleomargarine themselves, but see no reason why those who want to use it should not be permitted to purchase it.

From their premises, the conclusions reached are logical. The trouble is that the premises are false.

It is perfectly safe to say that not ten per cent of the oleomargarine which is made and sold, is placed before the final consumer for what it is. There is no way in which the exact figures can be ascertained. It is known, however, that in at least nine cases out of ten the retailer sells oleomargarine as butter. It is also known that the manufacturers sell immense quantities to hotels, restaurants and boarding houses, which later appears upon the tables as butter and is paid for as butter.

But the casuist says: If the substitute is of such quality that the consumer cannot detect the difference, what right has he to complain or how is he injured?

There are two answers to this question.

(1). He is injured by being required to pay more than he ought. Oleomargarine, when sold on its own merits, is always much cheaper than butter. It can easily be afforded for less than half the lowest market price for butter. The laboring man who is deceived into purchasing oleomargarine is swindled out of ten cents on every pound that is weighed out to him. The keeper of a hotel, restaurant or boarding house, who serves oleomargarine makes a dishonest ten cents on every pound that he can deceive his patrons into eating.

(2). Oleomargarine is not a healthful food. Every chemist who assumes to pronounce to the contrary, goes outside of his science, and his opinion in that behalf is of no more value than that of a stage driver. Chemistry cannot determine that or any other similar question.

Chemistry cannot determine, for example, that arsenic is poisonous or that sugar is not poisonous. The chemist can analyze a substance and say that arsenic is or is not present, and then, relying upon the tables furnished by others, can say whether the quantity found is sufficient to destroy life. He can analyze oleomargarine and tell us with great accuracy just what its components are and in what proportion they are present, but only the human stomach, after it has been fed with oleomargarine for months, can pronounce upon its healthfulness. And it does not follow because a robust man, working ten to fifteen hours per day, can eat oleomargarine with impunity, that others under different circumstances could do so.

The following clipping from *The* (London) *Dairy* of August 15th, fully corroborates all that we have said above:

A little incident reported from Bristol would, says the "*Evening Standard*," have come in usefully during the debate upon the Food and Drugs Act, a few days ago. Emily Stallard, an inhabitant of that ancient and famous city, was summoned by the police for selling margarine as butter. Her methods are worth noting. She bought "large quantities" of the compound, took it home, and made it into neat "pats" with an acorn on the top. Then she dressed herself up as a farmer's wife, with a clean cap and a check apron, arranged the pats nicely in a basket with a white cloth, and perambulated the town offering "country butter" of her own making. Who would not feel tempted to buy from an honest and industrious farmer's wife, compelled by agricultural depression to hawk her own produce about the streets? Emily Stallard did uncommonly well, no doubt, until her little trick was discovered—when she had to pay twenty pounds and costs. How many of her sort are still carrying on the business? But it is asserted by a member of the Somerset County Council, who has been making careful inquiries, that the working classes are not great consumers of margarine. As Mr. Edmund Hill learns, it is public institutions, convents, schools, business establishments where the employes are boarded, that use the stuff. It seems not unlikely. In such places people must eat what is provided. But Mr. Hill has made another curious observation. At the Wells Asylum, with which he is connected as a member of the County Council, the inmates receive margarine. In the asylums of Dorset, Wilts, and Hants—the adjoining counties—butter is furnished, and the death rate at Wells is thirty per cent higher. At Taunton, whilst the patients had butter, there were eleven deaths in thirteen months; margarine was substituted, and in nine months the deaths rose to twenty-two.

The hospital experience recounted above, is in strict accord with French investigations, where, after fair trial, oleomargarine was condemned as unhealthful, and its use prohibited in hospitals. In the United States it has been observed in public institutions of various kinds, and in the boarding schools for girls, that the use of oleomargarine lowered the vitality of the inmates very perceptibly.

And now that an effort is being made to have Congress enact a law which will either put the unholy profits at present made by dealers in oleomargarine into the public treasury, or stop them altogether, there is a great hue and cry that this is class legislation in favor of dairymen. Dairymen do not deny that they are interested in the proposed legislation, or that it will not benefit them. But their interest is legitimate, and the expected benefit no more than they have a right to demand. From whatever point of view it is approached, oleomargarine depends upon fraud and deceit for its distribution and sale. If it were not for this fraud and deceit, not one pound would be consumed where now a thousand pounds are used. Whenever and wherever it is made to resemble butter, it should be made to pay a tax equal to the difference in its cost and the average price of butter. If, as its makers claim, it is superior to butter and there is a legitimate demand for it in place of butter, they can well afford to pay this tax, and the government needs the revenue to be derived therefrom. On the contrary, if there is no legitimate demand for it, if consumers will not knowingly buy or use it, is it not consistent with good morals and sound public policy to put such a tax upon it as will remove all temptation to dispose of it for what it is not?

If, as some courts are disposed to hold, it is a legitimate article of commerce, it can well afford to pay a tax of ten cents per pound. If, on the contrary, and as the actual facts are, it is not a legitimate article of commerce, and the traffic in it is maintained by wholesale deception and fraud, it is competent for congress to tax it into the oblivion it so richly merits.

CHEESE AS A SUBSTITUTE FOR MEAT.

The increased cost of meat is a question of great interest to the average consumer of the product of the steer. In many cases it may mean a decided decrease in the actual amount of meat used, and a replacing it with other forms of food, cheaper in price, but of less nutritive value, and consequently of greater actual cost to the consumer.

The present outlook is that the high price of meat will be kept up for a number of months at least, and perhaps for more than a year, reports showed a decided decrease in the number of beef cattle on the ranges and elsewhere available for food purposes. Good beef cannot be produced in a few months, nor can the market be supplied by importations from other countries, and this will cause people to look carefully for a substitute for their accustomed food. Under these conditions, dairymen should make special efforts to bring before the constantly increasing consumers, the high nutritive value of dairy products, calling especial attention to the cheapness, palatability and food value of such products when compared with the best that the butcher can produce.

It is an invariable rule that the working man in this country eats meat every day, always once, sometimes three times, and the necessity of such food has got to be beyond dispute among the majority of our people. The cheapness of meat and the ease with which it has been produced has made it a universal food, and in consequence other articles of greater value, and at the same time cheaper in price, pound for pound, have been neglected, partly through custom and partly for want of pushing by powerful companies, but perhaps as much as anything through want of knowledge of the methods of preparation and use.

FOOD VALUE OF MILK.

It is hardly necessary to explain the great food value of milk; that it is a complete food for growing children, as well as animals, is a well known fact. It contains every ingredient necessary either for the growth or sustenance of the human body. Three and one-half quarts of new milk (costing 17½ cents) will supply the food requirements and daily wants of a full grown man. An equal supply of well balanced food would require in the form of beef, 3.6 pounds, if all the necessary food ingredients are to be supplied. This would cost in the neighborhood of fifty cents, if there was no waste in the meat. If bone and inedible parts are taken into account, the cost would be considerably larger.

In spite of this advantage of milk over meat, both in cost and value, there are but few families in the country that do not skimp the milk supply to buy beef—being held fast in the laws of custom and prejudice that decide that beef must be more valuable than milk as one is a solid, the other a liquid. The fact is, however, that 3½ pounds of milk, costing (at 6 cents per quart) 10.5 cents, is worth as much for food as one pound of boneless beef. And when we consider that at least 15% of beef is

waste and useless for food, the economy of milk becomes still more apparent.

FOOD VALUE OF CHEESE.

Without an exception, cheese is the most concentrated food known. Roughly speaking, it is composed of one-third water, one-third fat and one-third protein. The following table shows the composition of the digestible nutrients present in cheese and sirloin steak:

	Cheese.	*Sirloin Steak.*
Water	30.2	48.3
Protein	28.3	15.0 } Digestible
Fat	35.5	16.4 } Nutrients.
Waste	—	19.5

It appears from the foregoing that cheese has only two-thirds as much water as the average beef, has twice as much protein (muscle forming material) and about twice as much heat producing material. The waste or inedible proportion in cheese is very small, being but a fraction of a per cent of the amount of food bought, whereas in beef, it averages twenty per cent waste, and may, in the cheaper portions, amount to as much as fifty or sixty per cent.

If we take into account the edible part of meat alone, we find that a pound of cheese is equal to more than two pounds of meat, and in comparison with the meat as bought, where the waste must be considered, at least twenty per cent more must be taken from the value of the meat.

At present prices, a dollar's worth of cheese is worth nearly $2.50 worth of beef steak, and the man who finds it difficult to make both ends meet should, in the light of the above figures, endeavor to make the process easier by including cheese in the circle of his daily food.

By far the majority of consumers look upon cheese as an article to be used sparingly, and as an article of luxury rather than food. This idea comes partly from habit, partly from the quality of the article as found in too many cases, but perhaps from a want of knowledge of the methods of preparation in such a manner as to make it take the place of the more expensive meats, and thus appear on the table as the principle dish in place of its usual position of an appetizer at the end of the meal.

There are numberless ways and methods for the cooking of meats and it is perhaps from its former abundance that meat has taken so prominent a place in our diet, leaving cheese (more valuable, yet not so well known) to a lower place on the list of foods. But with the advanced price of meat should come a greater attention to cheese as a valuable and cheap food, and also better and improved methods of manufacture, handling, and more especially of cooking in appetizing ways.

As a rule, the cook books give but little attention to the last question, contenting themselves with a few perfunctory allusions to cheese cooking, and yet the methods to be used are simple and the result is an excellent series of appetizing dishes. Williams, in his "Chemistry of Cookery," gives the following methods for cooking cheese: Take a quarter of a pound of grated cheese; add to it a gill of milk in which is dissolved ¼ teaspoonful of cooking soda, with mustard, salt and pepper to taste. Heat the mixture carefully until the cheese is completely dissolved. Then beat up three eggs, and add this to the solution of cheese, stirring well. Pour into a shallow, buttered dish and bake until nearly solid.

2. Take slices of bread and soak them in a batter made of eggs and milk; then place the slices of soaked bread in a dish and cover each slice with a thick coating of grated cheese. Add another layer of bread and one of cheese until the dish is full. Pour surplus batter over the top layer and bake in a slow oven. A small amount of cooking soda may be used as in the first recipe.

It will be noticed that in both of these methods, cooking soda is used. This is for the purpose of bringing the cheese into solution and mixing it evenly through the mass, thus preventing the formation of the tough, leathery curds which come from the heating of cheese by itself. There is no doubt that if the average consumer could obtain good cheese and then have it placed before him in some appetizing dish, as above given, the consumption of this article of food would be greatly increased, both to the benefit of the consumer and the dairyman.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

FEEDING STANDARDS FOR MILCH COWS.

Dry matter.	DIGESTIBLE NUTRIENTS *Protein.*	*Carbohydrates.*	*Ether extract.*
lbs.	lbs.	lbs.	lbs.
23 to 28	2.0 to 2.5	12 to 15.0	0.5 to 0.8

FOR FALL PASTURE.

Please advise us what you would recommend for a fall pasture for milch cows, also best time to sow, etc. Do you consider rye a good pasture feed for milch cows?

St. Louis, Mo. S. D. Co.

Rye makes a very good pasture, but is hardly equal in our opinion to oats or barley, unless it is expected to harvest a crop next summer from this fall's seeding. Sow at different times so as to secure a succession of fresh feed. It would not be amiss to add some clover seed. Crimson clover is recommended for this purpose.

MIXED SILAGE COMPARED WITH TIMOTHY HAY.

Can you tell me the value, as compared with timothy hay, of ensilage, of which two-thirds is whole corn, and one-third soja beans. Ensilage was in good condition. W. D. T.

Cambridge, O.

The digestible nutrients contained in one hundred pounds each of average timothy hay and such silage as is described above, are shown in the following table:

	Timothy hay.	*Mixed silage.*
Protein	2.8 lbs.	1.77 lbs.
Carbohydrates	43.4 lbs.	12.20 lbs.
Fat	1.4 lbs.	.35 lbs.

This would indicate that for purely nutritive purposes, the hay would be worth approximately three times as much as the silage, but if we take into consideration, their relative milk producing value, which is in large degree indicated by the relative amount of digestible protein in each, the ratio is materially reduced, and two to one would be nearer the truth.

When it is remembered that one can easily produce five times as much silage as hay per acre, the great economy of the silo comes out in bold relief.

WHERE CAN PRIME COW HAY BE HAD?

Is alfalfa or any really prime cow hay on the market? If so kindly tell me where I can buy it.

I keep but one cow; she is now at pasture in pear orchard. Are the pears that fall, also apples, detrimental to her in any way?

Southold, N. Y. W. H. H. G.

We do not think the best hay for milch cows is very often sent to the cities. The demand there is not sufficient to justify it. Very likely, if one should go to a hay dealer in the city and prefer a special request that he obtain a few bales of clover hay, he could arrange to have them shipped with balance of order.

The fallen fruit will not be likely to injure a cow, unless there is too much of it. The amount she should be permitted to eat should be limited, certainly not exceeding a half bushel daily. There is also danger of choking, especially if the cow is hurried when eating; or an attempt is made to drive her away from the tempting food.

A MASSACHUSETTS DROUTH RATION WANTED.

Will you please give me a ration for butter from the following named feeds: Bran, corn and cob meal, cotton seed meal.

Pasture is poor and I am feeding corn stalks, but dry weather has hurt them, and cows do not seem to be doing as well as they should. G. S.

Southhampton, Mass.

The foregoing represents the condition of thousands of dairymen in all parts of the world. When we consider the almost countless number of dairymen who will not be advised, who will not even respectfully consider the suggestions submitted to them from time to time in these columns, and by others who have made dairy problems a special study for years, we are discouraged and despondent. In such moments we turn to the other side of the picture, turn our eyes to the right and the left and the front, instead of looking to the rear, and we see a constantly increasing company of earnest, active, progressive, thinking men and women, some of them skirmishing far in advance and occasionally sacrificing themselves in pioneering the advance against ignorance, superstition and lethargy, and others in the front rank of the advancing army, and we gather new hope and inspiration.

Prevention is better than cure. It is comparatively easy by wise forethought and fore-*action* to prevent, for example, the ravages of yellow fever, as was demonstrated by Gen. Butler in New Orleans in 1862–63, and by Gen. Wood in Santiago this present year; but once an epidemic is established, it must run its course.

We may not be able to control the seasons, or command the clouds to give or withhold rain, as we may wish, but we can provide in advance for these seasons of drouth by building summer silos and filling them with corn a year in advance, or with clover in June. It is of course too late for our friend to help himself in this way this year, but his present embarrasment should be a warning to others as well as himself. Read what J. E. G., of Ontario, says elsewhere in this issue, and let his experience provoke you to adopt his methods.

Our friend must consider at this time, especially if his cows are not to be fresh this fall, that he must feed them now quite as much with a view to what they ought to produce through the fall and early winter, as for present yield. When a shrinkage in the milk flow is once firmly established, it is practically impossible to obtain a normal flow again. Full feed may produce some improvement, but there will remain a large per cent of permanent shrinkage.

On the assumption that the pastures and the corn stalks furnish but little milk making material, he may find it necessary to feed as much as ten pounds of grain daily. In that event we would suggest four pounds bran, four pounds corn and cob meal and two pounds of cotton seed meal. Such a combination would supply approximately three fourths of the protein required, and other digestible nutrients as follows:

Protein	1.50 lbs.
Carbohydrates	4.40 "
Ether extract (fat)	.46 "

If, as is probable, these cows are receiving a smaller allowance at present, increase the amount gradually and note results. Do not expect the cow to respond at once, any more than you would expect a run down and tired horse to respond in one day to increased feed. Be encouraged, if at the end of a week or ten days there is a sensible improvement, and keep increasing the daily allowance of feed as long as improvement in yield can be observed.

TO PREVENT SILAGE SPOILING WHERE ONLY A SMALL AMOUNT IS REMOVED DAILY.

Will you please advise if silage, as ordinarily put up in a round silo, will decay, provided not more than one inch is used from the upper surface each twenty-four hours. In case the silage is likely to spoil when so thin a layer is removed in each twenty-four hours, the question arises as to the best plan to prevent decay setting in. Our silo is so large that the number of head of stock kept cannot consume more than one inch below the upper surface each day, and we are anxious to know in a case of this kind, if the silage is likely to spoil, what course can be taken to preserve it. C. J. H.

Detroit, Mich.

There is no question that in cases of this kind the silage will be materially injured, especially when the temperature is not pretty low, although not "spoiled" in the general acceptance of the term. To prevent this, recourse must be had to covering of some kind that will measurably keep the air from the surface of the silage. A good arrangement, as well for convenience as for efficiency, would be a piece of old sail cloth or other heavy canvas or tarpaulin same size as silo, to spread over silage. When the time for removing the silage arrives, turn back the canvas half way across the silo, remove the amount required, and then replace the canvas. Of course any other device which will exclude the air and can be readily moved will answer the same purpose.

CROSS BREEDING A LOTTERY.

Please tell me what the results would be to cross a registered or grade Holstein cow with a registered Ayrshire bull. The Jersey and Ayrshire is said to make a good cross, but I have never been able to find out any thing about the others. W. J. R.

McKeesport, Pa.

No one can tell in advance what will be the result of cross breeding. We know—or at least we think we know—that in line breeding we are pretty sure the progeny will resemble the parents or other ancestors. Not infrequently they take back through several generations and in too many particulars reproduce the faults and peculiarities of their plebeian progenitors. The improved qualities which have been obtained by years of careful selection and appropriate environment until definite breed characteristics have been established are, for example, like those of an improved variety of corn. They may not include everything that is desirable, but the bringing together of two diverse breeds of cattle is likely to result in much the same confusion that would result from planting different varieties of corn side by side. The first cross would, doubtless, produce some excellent animals, a part of them inheriting more largely from one breed, a part from the other breed and not a few reverting back to the primitive traits of both. In other words, there is a conflict between the alien elements and when they are so evenly matched that neither can gain ascendency, they become mutually destructive and thus open the way for the re-establishment of the original scrub tendencies common to both. Thus cross breeding is a lottery in which there are occasional prizes and numerous blanks.

FLAX SEED MEAL FOR CALVES.

Please give me your opinion of flax seed meal, boiled, fed to calves in skim milk, and what quantity per day. SUBSCRIBER.

Madison, N. J.

Flax seed meal, which we understand to be ground flax seed, and not the ordinary linseed oil meal of commerce, is an ideal supplement to skim milk for calf feeding, provided it is not given to excess. One should commence with a very moderate allowance, say, a tablespoonful with each meal, and, taking careful note of the results and being governed thereby, gradually increase the amount as the condition and growth of the calf may seem to demand. Bear in mind that the calf, whether male or female, intended for dairy purposes, should not be allowed to become veal fat, and that the development of a capacious stomach is much to be desired. Skim milk with a limited amount of ground flax seed, and all the nice, bright hay it will eat, makes a first-class ration. A few whole oats may be added, and some bran also, because these are bulky foods, and not deficient in muscle and bone forming elements.

Mr. Wheaton's Canadian Dairy Notes.

Canadian Dairy Schools.

ED. HOARD'S DAIRYMAN:—The dairy school announcements, which appear this week, remind us that the summer season will soon be over, and that the winter with its opportunities for training the mind and storing up information for future work, is close at hand. How times have changed in recent years, in this particular, in regard to dairying. Only a comparatively short period has elapsed since the cheese and butter maker found the winter time hanging heavily on his hands, with nothing much to do, but loaf around the country village, and, perhaps, forget a great portion of the knowledge which the previous summer's operation had given them.

But with the advent of the dairy school, and the demand for more skilled and intelligent service in our cheese factories and creameries, all this has been changed. The maker to-day has opportunities which the maker of fifteen or twenty years ago never dreamed of. And what is better still, this demand for men whose knowledge of their business goes away beyond the mere mechanical ways of doing things, makes it necessary that every maker should take advantage of these opportunities.

When the dairy schools were first established in this province, there were some who were of the opinion, that their usefulness would be gone, after a few years, when all the makers had taken the course. But several years have elapsed since their inauguration, and as far as we can see, there is just as much interest shown, and as great a necessity for them, as there ever was. In fact, the constantly increasing demand for a better quality of product, makes these training institutions for the cheese and butter maker a greater necessity than ever.

Though we have not reached the stage, in this country, when no cheese factory or creamery will engage a maker unless he can show a certificate of having taken a course, and passed a satisfactory examination, at one of the dairy schools, yet we believe the time is drawing nearer, when such will be the case; and the sooner it comes the better. The maker of to-day must not only know how to make butter and cheese, but must also know the reason for doing things connected with the process. The "know how" and the "why" of doing things has become an absolute necessity in good cheese and butter making.

Of course, we do not contend that every person sent out from our dairy schools will be a first-class man. It would be a miracle if such were the case. It is just as reasonable to expect that every pupil who attends our collegiate institutes and higher educational institutions, and receives a certificate which permits him to teach in the public school, is going to make a first-class teacher, as it is to expect that every student at our dairy schools is going to make a first-class maker. As there are comparative failures in the first instance, so there will be in the second.

But what we do contend for, is that every thing else considered, a term at the dairy school will make a man a better cheese and butter maker than if he had never attended. A dairy school course should prove a good test for a maker. If, after taking the course, and after having passed the examination, he then proves a failure as a maker, the individual may take it for granted that he hasn't the qualities in his make-up that are essential in a good cheese or butter maker, and the sooner he quits the business, and adopts some other vocation, the better for himself, and the industry as well.

But while there have been such failures as we have described, we are glad to report that they are comparatively few. Experience with dairy school students for several years back, has shown that the best, the most skilled, and the most intelligent of the younger class of makers who are operating factories today, are those who have had a dairy school training. There is something in the influence and teaching of a dairy school, outside of the mere daily routine of lectures and practical work, which makes a young maker, especially, think more of the business in which he is engaged, and which inspires him to look deeper into things and to make a greater effort to be at the top in his calling.

But we have, perhaps, moralized too long upon the school and the maker's relation to it. Let us return to the announcements already referred to. The first one is that of the Provincial Dairy School in connection with the Ontario Agricultural College at Guelph. This opens on December 4th and will continue till March 23rd, 1900. There will be two sessions. The first, beginning on December 4th and closing on December 22d, will be a special creamery course to aid makers who cannot spare the time for the full course, and who wish to operate creameries for a portion of the winter and the early spring.

The second session, which will cover the full courses in the factory and home dairy departments, will open on January 3rd and close on March 23rd.

The second announcement is that of the Easton Dairy School at Kingston, Ont., which will open on December 4th and close on April 7th, 1900. This period will be divided into four courses of three weeks each, and one of six weeks duration. The shorter terms are arranged to meet the needs of makers who do not wish to take the full course, and of those who have already taken it, but wish to brush up a bit during the winter months. With these opportunities, no maker should be without the great assistance which a dairy school training will give him.

The readers of the DAIRYMAN are familiar with the work that has been done in Prince Edward Island, by the Dominion Government, under the direction of Professor Robertson, in establishing the dairy industry there, and how successful it has been.

The first cheese factory was established in 1892, and last year there were thirty-four co-operative cheese factories, and twenty-three co-operative creameries in successful operation, and the total value of the butter and cheese available for export was $364,557.63.

The same line of work is to be started in Nova Scotia, and the Dairy Commissioner leaves next week to make final arrangements. No co-operative cheese factories will be started by the government, as there are already a number of these in successful operation. The work will be confined to co-operative creameries, which will be operated during the coming winter, in order to demonstrate the possibilities of the winter dairy business in that portion of the Dominion.

J. W. WHEATON.

Toronto, Canada.

Note and Comment.

Some Dairy Intelligence.—The Wisconsin Station Cows.—Effects of the City Cream Trade.—Quality of Milk at Factory.

ED. HOARD'S DAIRYMAN:—It must be very refreshing to the makers of HOARD'S DAIRYMAN, to read the views of intelligent dairymen, especially of the Badger State itself, and note how it has elevated the dairy tone of the state in question, if not all of the entire country. As an instance, we insert here some Wisconsin dairy lore, found in a late issue of the *Philadelphia Farmer*, and commend it as a choice bit of dairy literature, that ought to make its author famous.

G. W. WEBB, Arcadia, Wis.—I believe that the average farmer should breed from stock that will make good beef when ready for market. A full-blooded sire is all that is necessary. Many of the most successful farmers here formerly used Short-horn sires, and by careful selection got cows that were profitable for butter as well as beef. Nearly all of them, through the influence of the Jersey papers, changed their herds by using Jersey or Guernsey bulls. They have stuck to the change long enough to give it a fair trial, and have found that they made a mistake, and are getting back to the beef breeds as fast as possible. One can, only by long and careful selection, get a profitable herd of cows from the butter breeds. Not many first-class butter cows are found among the butter breeds. One can be found more frequently in the beef breeds. One argument of the Jersey men was the less amount of feed required to keep a Jersey. The fact is that a Jersey is a good feeder, and will remain thin with the same amount that will keep a good Short-horn grade in good condition, and giving a good flow of milk. So far as feed is concerned there is no saving in having a little Jersey, for they are always hungry, and are the happiest animals while eating, I have seen.

Yesterday we went to a Summer Institute and as usual picked up a point or two. One dairyman was contending that "he wanted cows that would get fat while they were being milked, so that in case he wanted to sell them, they would go for beef. The retort was that a cow rarely did two things well at the same time, and if she fattened, it was at the expense of milk, and at eighty cents per hundred for milk, it made pretty dear beef in comparison." "Well, I don't sell the beef, I want to keep the cow for several years." "Then what good is the beef, if you can't sell it along with the milk?" But you see, a cow that is fattening along with milk giving, always gives larger messes of milk, and holds out longer."

"Now it has been proven, with a lusty growing steer and a good dairy cow, that it only takes two pounds more dry, feed matter to make a pound of twenty cent butter than it does a pound of five cent live beef. What will be the cost of that cow beef of yours when you come to sell the cow at ten years old?" "Well, it isn't that way with my cows. One of my fat cows milks the year round, and gives a good mess. 'Yes, that's a fact,' said a neighbor, 'but say Jim! what 'er the other fourteen a doin' six months of the year 'sides eating hay."

* * *

The Wisconsin *Bulletin*, Number 75 is a valuable contribution to dairy literature, and its compilation has increased the debt, the dairymen owe Prof. Farrington, not a little. One thing conspicuous about it is the confirmation of what we have observed for years in our own herd, that it was the smaller and poorer milkers that gave out first, and dried up, and boarded the rest of the year. We have in our life owned three cows that were away up in yield, and they were each year round milkers, with here and there a cow that started out with great flow and rounded up with beef as her final contribution to the dairy supply of the season.

The pictures of cows No. 1, No. 42 and No. 55 are particularly interesting to a student of dairy types and functions, especially so if they are to be sized up with "Terry's Pet" page 447, and other cows of like conformation, as guides in dairy form; but if No. 42 is to go into the class with the "400," there has got to be some "redhedity" hunted up to go with that great depth of barrel, and pressed digestive ability, or the occupation of the dairy judge is gone, and when No. 32 is set up, this "brother to the ox"—begging the poet's pardon—is ready to let an old farmer friend of mine have the floor, when he says, "tain't the breed so much as the cow herself, and all there is of a cow any way is a good, big square udder, back sloping ribs, an incurving, cat-ham thigh, a backbone that sort 'o sags, and a somewhat of a deep and roomy paunch," yet cannot see that he has picked out five of brother Hoard's best "pinters" in the selection of a dairy cow.

The length of hip in Nos. 34 and 55 is remarkable, as well as the apparent wide space of the shoulders at the brisket, in both points, showing large maternal functions, and strong vitality, accounting possibly for the large fat production.

It is to be noticed that the good cows all milked over 300 days—No. 34, full 350; all of which goes to show that there are cows and cows, as well as some others that crop out here and there, as well as at Chicago; though it begins to look as if the Swifts, and other dairymen (?) of that village were soon to hold the record for butter production with their dual-purpose animals.

"Think of Ease But Work On."

If your blood is impure you cannot even "think of ease." The blood is the greatest sustainer of the body and when you make it pure by taking Hood's Sarsaparilla you have the perfect health in which even hard work becomes easy.

Hood's Sarsaparilla
Never Disappoints

It is a matter of great regret that we hear that the famous Mt. Pleasant creamery of Southeast Ohio has closed its doors, and the plant has been sold, and the affairs of the company wound up. Without doubt it was, in its products offered to the market, at the very front of the creameries of the central states, and managed as only Quakers can, and every cow contributing to its supply of milk a Jersey, there was never any discount on its butter.

But the fate that has overtaken other concerns, came over the Jefferson Co. hills, and in spite of George Scott and the other friends, the creamery received its "go to." It was the same story again, increasing demand for cream for the city, at a price that set butter making aside, and the cheapening of hand separators, made taking milk to a central just to be creamed, out of the question.

Fifty cents per gallon for cream at the farm was the cause of the demise of this creamery, as well as of others, and we think that the end is not in sight, either in demand for cream, or the dissolution of creameries. In some sections the creamery is making its gravity set milk into cheese that are branded and sold as skims, and bringing a fair price, seven cents this year; the concerns are holding on pretty well, and some of these creameries are leading the market in price paid for milk. The concern near here is paying eighty cents against the cheese factories sixty-five and seventy cents.

***

We believe that the factoryman who stipulated in the contract that the party on demand should prove the purity of the milk he offered, by drinking the last half pint of milk in the can, has hit upon a good scheme in securing a better and purer quality of milk at his factory. That all milk that is brought is strictly clean and uncontaminated, is not believed by those who stand at the weigh can 730 times in the year. Some have asserted that the only thing that they have failed to see or discover in the milk, in that time, has been the leg of the cow herself. Of course all that will disolve has liquified in the transporting, and what does not, is run into the vat strainer, and 2,000 or so pounds more of milk run over it—whatever *it* may include—and then the maker is ready to produce goods with *dairy* flavor, without further recourse to cultures.

While not all are guilty, there are a lot of careless patrons, abetted by factorymen who care as little for cleanliness and tidy surroundings as Alaska Indians, and if the two classes should be relegated by a great common law, into obscurity, and be made to subsist upon the cheese and butter made from the last milk in the cans, for the next thirteen moons, there would be somewhat of a change.

Not long since we saw a can of milk turned into the weigh can that would have

Not a Preservative

but a preventive. If you would have your milk keep sweet longer and be free from all objectionable odors, use a CHAMPION Milk Cooler-Aerator. It does its work perfectly and it's use does'nt violate any law—it doesn't need to be used on the sly. Our book "Milk" is free.

CHAMPION MILK COOLER CO.,
67 Main Street, - Cortland, N. Y.

caused the Sphynx to blush and shut its one well eye, and yet the factoryman took it, and said later on, that if he did not, the fellow would take his milk over to Willie Waldorf Astor's concern, and he would be a patron short.

Here is the whole secret. Too many little factories, just able to exist, simply a living for the owner, and to lose a patron with his 50,000 pounds of milk a season, meant to him quite a sum of money.

What is wanted is a pooling of factorymen and the acceptance only of milk off its fat basis and purity, and making it impossible for a patron to change factories if his milk and its quality and purity are called into question. There are untold numbers of factories with A No. 1 patrons and good equipped factories, and then on the other hand, there are others.

If the average board of health did not "slop over" so often; and so frequently quarantine, and tuberculin spook, it would be a good thing for the dairy interests of the United States to put our factories, creameries, and skim stations under certain reasonable sanitation rules, and regulations, and the patron, can, stable, and milk offered, under inspection, and have clean material to start with, out of which to make butter and cheese; then if the maker had a clean record and overalls, and a certificate of proficiency from a good dairy school; and the whey and slop of the creamery sewered into Lake Apmoojenegamook in Maine, instead of being drawn home in milk cans, we might improve to a great extent a considerable portion of our cheese and butter product that is now doing serious damage to the reputation of our better class of dairy goods.

JOHN GOULD.

TUBERCULIN TESTING ON CLOVER FARM

An Interesting Letter from the Proprietor, H. B. Gurler.

Some time since we noticed the following in an Elgin, Illinois, paper:

H. B. Gurler has had his cows tested for tuberculosis. Cows valued at $700, that did not stand the test, were ordered killed. As an experiment, he killed a calf that had been fed on milk from a cow having tuberculosis. The calf was found to be diseased. Mr. Gurler's is undoubtedly the ideal dairy of Illinois, all of which goes to prove that milk is not to be depended on, from whatever source it comes. As a disease medium milk is a great factor.

The clipping was sent to Mr. Gurler with request that he give us the facts in the case. He writes as follows:

ED. HOARD'S DAIRYMAN:—On my return from a short vacation I find yours of the 19th on my desk.

Seven to eight hundred dollars covers the value of all the cattle killed on Clover Farm that were convicted of tuberculosis by the tuberculin test. I had never found an animal grown on Clover Farm to be tuberculous until last January, when some calves that were being fed on skim milk from a skimming station, were found to be tuberculous. I cannot prove that they contracted the disease from this source, but I cannot conceive any other way that they could have acquired it. They were dropped by cows that had been tested with tuberculin. So I am reasonably sure the disease was contracted from some source.

After four and a half years of experience with the tuberculin test, I am quite confident of its reliability.

There have been about 900 tests made with tuberculin on Clover Farm and only one animal that passed the first test has ever reacted on the second or any later test.

You are at liberty to use these facts in the matter if you desire. The dairymen are not in a mood to receive kindly the hard facts in the case. They will reach this condition later. H. B. GURLER.

There is a good deal more unsaid than said, more that is suggested than written, in the above statement by Mr. Gurler. It should be understood in the first place that he is one of the advanced and representative dairy farmers of the United States. Further, he is the author of that most excellent book, "American Dairying." Mr. Gurler is not only a man of ability and thorough dairy intelligence, but he is a man of strong and reliable character as well as eminently conservative. All these characteristics may well cause men, who are seeking light on this absorbing question of tuberculosis, to ponder well on what he says.

The farmers who blindly oppose the testing of their cows, are simply hugging a delusion to their breasts. They have a right, however, to insist that none but the skilled practitioners and men of thorough honesty shall be employed by the authorities to make the tests. Too often, we fear, some half educated veterinarian comes to the front and does more harm than good in his testing of cows.

Another thing is worth remembering, that Mr. Gurler speaks of, that is, his exemption from infection among the cattle he has raised himself. This is due to the fact that he took pains to have only healthy cows in his herd. Mr. Gurler believes that he cannot afford to raise or keep tuberculous cows, not alone because he is selling their milk, but for the additional reason that good health in his herd is a matter of value to him. Indifference in this respect, so often seen among cattle owners, is a serious drawback to their own profit, because of the resulting loss of cattle.

Cedar Hill Jersey Farm Notes.

For Next Winter.—Poultry on the Dairy Farm.

ED. HOARD'S DAIRYMAN:—All signs point to the return of fall and winter once more. Ten years ago we would have dreaded the return of cold weather, but to-day the up-to-date dairyman, with his improved methods, rather looks for cold weather with feelings of pleasure. He is saved many little annoyances and much work, while the eight months of fall and winter will show more profit from his herd than the hot, dry months of summer.

Warm, light barns, plenty of south side places for cows to bask in on winter days, water with temperature raised above sixty degrees, ensilage balanced with some of the grains, and all the above balanced with a carefully bred herd of working cows, will yield good returns if the robins are not nesting.

Our water supply will be warmed by steam this winter by running a pipe into the supply cistern. We have over four hundred feet of continuous tight fences and buildings for our cows to take their sun baths on winter days.

We have a 25×27 foot silo nearly completed. It is built of 2×4 spruce pieces twenty-six feet long; it is being put up by our own boys. They have not put on hoops yet and will not till the last thing. We have solved the problem how to put up a stave silo, so that all joints will be tight and no springing can occur. We use forty-penny spikes, drive them through the 2×4's the wide way, nailing each piece to the one already in place. This makes a good job, both in building and after it is built, as our 2×4's are really only 2×3¼ inches, our spikes penetrate the second piece 1½ inches. I am sure this will greatly strengthen our silo.

Institutes and Dairy Conventions are again making dates, and Buff Jersey is getting his share of requests to be present. We are always glad to meet representative farmers and dairymen at these meetings. Everyone learns something new and the change is beneficial. In our case we must use moderation as our home work is taking up our t me.

* * *

POULTRY ON THE DAIRY FARM.

Who among the DAIRYMAN readers are making poultry one of the branches. Cedar Hill farm will make the poultry department next to the herd from now on. We have this season hatched five hundred pullets of our two popular breeds, Leghorns and Barred Plymouth Rocks, so that by cold weather we will have a flock of young laying hens to consume a large amount of our skim milk that would be, under the average conditions on our dairy farms, fed to a lot of hogs that would be apt to die with cholera about the time we wished to realize on them.

This morning I gave our various yards of fowls twelve gallons of skim milk to drink and mixed their feed with six gallons more. I am sure no better use could be made of this milk. On September first we will load our two incubators with five hundred eggs so that we can stock our brooder house with chickens for the mid-winter market, and also to regale my many friends who come from far and near to visit. "BUFF JERSEY."

THE BOSTON CHAMBER OF COMMERCE ON THE TEN CENT TAX.

At a special meeting of the Boston Chamber of Commerce, the following resolution was unanimously adopted:

Resolved, That we believe that a tax of ten cents per pound by the United States Government on colored oleomargarine would in no way conflict with our present State anti-color law, and would additionally protect pure butter from unjust competition with oleomargarine. As merchants and dealers in butter, we believe a tax of ten cents per pound sufficient.

The people are lining up with the National Dairy Union on this question. Members of Congress will "hear the joyful sound" in due time.

The Falling Leaves Give Warning of Winter

So the falling of the hair tells of the approach of age and declining power.

No matter how barren the tree nor how leafless it may seem, you confidently expect leaves again. And why?

Because there is life at the roots.

So you need not worry about the falling of your hair, the threatened departure of youth and beauty. And why?

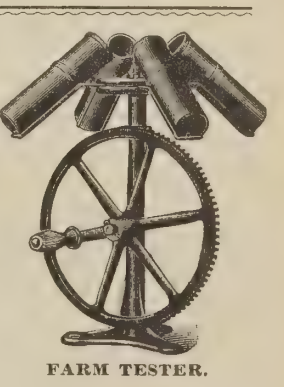
Because if there is a spark of life remaining in the roots of the hair

AYER'S HAIR VIGOR

will arouse it into healthy activity. The hair ceases to come out: it begins to grow: and the glory of your youth is restored to you.

We have a book on the Hair and its Diseases. It is free.

The Best Advice Free.



If you do not obtain all the benefits you expected from the use of the Vigor, write the doctor about it. Probably there is some difficulty with your general system which may be easily removed. Address,

DR. J. C. AYER, Lowell, Mass.

Be Careful

To read article on page 488, issue of Aug 4, HOARD'S DAIRYMAN, regarding the Use of Babcock Testers in Cheese Factories.

We were the first manufacturers to make a tester in which to test milk after the method devised by Dr. Babcock, and we have always retained the first place in the list of manufacturers. The Farm Style, Factory Hand Style or Factory Motor Tester are the best made. Full descriptive catalogue, with directions for operating, free.

Cement Floors for Stables

A Trial Subscriber Renews and Submits a Question.

ED. HOARD'S DAIRYMAN:—Having been a subscriber to your paper for the last three months, (on trial) I mail you to day under separate cover, my renewal to begin with September 1st, as I do not want to miss any papers.

I keep a small dairy of fifteen milch cows, and am building a new stable in which I wish to put a cement floor. Will you please give information in regard to mixing, and putting in cement, also foundation or bed, and would you advise putting in mangers before or after cementing. Mangers will be double, two cows together, and then a short partition, tie with chain around neck.

No. Kingsville, O. R. E. F.

This question was pretty well discussed by Prof. King and others at the last meeting of the Wisconsin Dairymen's Association, and we compile from that and other sources as follows:

1. Be sure to secure good drainage, and to this end cover the excavation four inches deep or more, with sand.

2. On this bed place a layer of concrete, made of seven parts coarse sand and gravel, one part Portland cement well mixed, dry, and then use just water enough to thoroughly dampen it, and mix again. After spreading this concrete, tamp it down quite solid, and until the water begins to show on the surface.

3. On the above as a foundation, spread a coat of cement mortar, two parts clean, coarse sand, to one part Portland cement, first mixed dry as above, and use only so much water as may be necessary to make the mortar spread readily, and make only a small amount at a time. Use a wood trowel or "float" to compact the mortar and force out the air, and do not smooth the surface.

4. Keep everything off the floor for at least twenty days, and keep it well sprinkled from time to time, to prevent too quick drying.

5, If mangers are made of cement, put them in at the time the floor is made; if of wood, not until the cement has hardened.

6. If common water lime is used, take about twice the quantity above specified for Portland cement.

Gold Medal Butter.

[Paper read before the Massachusetts Creamery Association by R. F. JAYNES.]

I commenced the butter business twenty-one years ago. Thirteen years I spent in New York, and when I left there six years ago and came to Vermont I thought I was quite a butter-maker. As I look back over those thirteen years I can see I was only starting on the road to my chosen profession. I expect to learn more about butter-making in the next five years than I have in the past twenty-one. And I tell you, boys, we can get some good ideas from each other here, and by experimenting on them derive a great deal of benefit from this meeting.

It will be easy for me to tell you how I make butter, but years of experience, and especially the experience this winter at the dairy school at Burlington, show that conditions vary, and you cannot make butter in just the same way everywhere. At Burlington I often churned at 54 to 56 degrees and had butter in fifteen to twenty minutes with only .06 to .12 per cent of fat in the buttermilk, while at home I have to churn forty to sixty minutes at 58 to 62 degrees, and leave .1 to .2 per cent of fat in the buttermilk.

I give the man that takes the milk strict orders not to take one can of milk that is off in any way.

We enjoy a reputation on our butter, second to none in uniformity. I often have butter-men in Boston ask why neighboring creameries have butter off every once in a while, while ours is always the same. To us this is a great benefit, as we cater only to the fancy trade and must have butter of fine quality every day.

Now, starting with good milk, if your strainer becomes dirty, change for a clean one; it is hurtful to sift new warm milk through dirt or filth. It is worse than patrons leaving their cans standing in the barn exposed to undesirable odors.

I separate milk at a temperature of 75 to 80 degrees, which leaves the cream 70 to 72 degrees when the run is done. I leave it at this temperature, stirring often, as it is impossible to get an exhaustive churning unless the cream is thoroughly mixed during the ripening process. I do not commence to cool it until it shows acid enough so I can cool it down to churning point and hold it there at least three hours before churning. I find that this is of more importance to produce an exhaustive churning than it is to the quality of the butter; why, I cannot tell.

I experimented on this a great deal at Burlington, and my highest tests of buttermilk were from cream not cooled the night before churning. I wish you would test your buttermilk from cream cooled just before churning and from cream that has stood at the churning point not less than three hours, and write me the results. I know of butter makers that cool their cream to churning point by putting ice directly into the cream in the churn and letting it cool down as they churn. I wish they would test their buttermilk and see what the results are. Most creamery men test skim milk often, but very few know anything about how their buttermilk tests.

Upon the right amount of acidity depends the flavor your trade demands. This is entirely a matter of individual judgment; some want a higher flavor, almost on the verge of acidity; to others high flavor means a flavor that comes from sour milk and butter milk; others desire a clean, pure milk flavor. The true odor of perfect butter is a mild, desirable flavor or combination of flavors, hard to describe and only met with in perfection under perfect conditions.

New York desires a flavor that comes from cream testing as high as .6 per cent, while my trade in and around Boston requiries a little over .4 per cent acidity. Right here, in my mind, is where you lay the corner stone upon which you must build your reputation. As flavor is about the only thing now that is scored off in our exhibits, to produce that desirable flavor depends upon condition of the milk or the ripening of the cream. I run a cream of about thirty-five per cent fat test and find it gives me a better flavor than a thinner cream. I will tell you why I think so. First, if milk is off in any way the more you have of it in the cream the more of the undesirable bacteria will be developed and season your butter. Then if the milk is good the trouble will be that the acid will coagulate the casein and turn it into cheese; a large amount of it will be taken up and absorbed by the globules of fat as they adhere to each other. Hence, you will have part butter and part cheese, which will give you that undesirable sour or cheesy flavor.

The butter globules are round and the surface tension keeps them separated one from another. They are supposed to be pure as they come from the cow, and are seasoned by the milk surrounding them. Now if we could take the globules out as soon as the milk was drawn from the cow and put them into a pickle made of pure pasteurized milk and keep them pure until we have a sufficient amount of acidity developed to give us the desired flavor, we ought to have a perfect butter. So for this reason I run my cream as free from milk as I can, and I find that the thirty-five per cent cream is as heavy as I can churn and have a sufficient amount of liquid in the churn to float the butter, and have it come in a granular form.

I would advise the butter makers of Massachusetts, that are not having satisfactory results to try running a cream of not less than thirty-five per cent fat; to try the Farrington and Ward test, and use an acidity of forty-five; keep cream in a clean, pure place, cool it to your churning point the last thing before you leave the creamery for the night; churn at a tempeature that will bring butter in about forty-five minutes in a granular form; wash once in a water not more than three degrees different from the churning temperature; work and salt about three quarter ounces to the pound. Unless your conditions are much different from mine, you ought to have a butter that will score for extras.

HUSK YOUR CORN, SHRED YOUR FODDER, SELL YOUR HAY.

A corn crop may be profitable without saving the fodder, but it will be twice as profitable if it is saved. The new method of handling corn saves the entire crop. The new way is to run all the corn through our **JANNEY COMMON SENSE Corn Husker and Fodder Shredder**

There can be no dreaded "corn stalk disease" where fodder is prepared with our machine. You can make a great deal of money husking for neighbors. Costs less than a third as much as a thresher, but makes more money.

Write for Free Catalogue.

It husks out all of the corn clean, and shreds all the fodder at the same time. Makes clean, healthful food, as the patented screen in the feed elevator takes out all the dust, dirt, smut, etc.

Go to your nearest dealer and see one.

JANNEY MANFG. CO., Box 29, OTTUMWA, IOWA.

It is important that everything about the dairy should be scrupulously clean, for the flavor that you want to develop will not come where bad odors are allowed to exist. Butter culture I never use. I develop my flavor every day just as I want it in my cream. If for any reason you should have bad milk or poor cream you should improve the flavor of your butter by using some good starter, rushing the cream along and getting it out of the bad company it is in as soon as possible; everyone is known by the company he keeps.

Making gold medal butter is not all that is needed for success in business. What good does it do to make an extra article if you cannot sell it for an extra price? To be able to do this it is necessary to visit the markets of our large cities and see your butter as others see it. It has been instructive to me to visit the butter rooms in Boston and study the wants of the customers as they come and go.

Not long ago a buyer came in and asked the salesman if he had anything extra, and the salesman said he had an extra extra, and started to show him a pile of tubs across the room, when the buyer stopped him and said, "No, I cannot use butter put up in such dirty looking tubs, no matter how good it is; it would be too hard to convince my trade that any one would put good butter in such dirty looking packages." He bought a poorer quality of butter that was more pleasing to the eye. After he went out I examined this butter, and found that it was a very fine goods, but the tubs had been handled with dirty hands and carried to the station in a dirty wagon; there was also butter on the outside of the tubs.

I cannot too strongly urge you all to be particular in putting up your butter, to have it neat and attractive to the eye. Do not neglect any of the small things, then you will not be as apt to forget the large ones. The first appearance goes a great ways towards forming one's opinion of anything. I visit my customers often to study their wants. I never have any argument with my trade. I give them just what they ask for and try to please them so well that they are willing to pay me an extra price, not only for the fine quality of the butter, but for the certainty that they will get what they want when they want it.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The offering of butter on Monday's Elgin Board of Trade, aggregated 7,860 pounds. All bids were at 21 cents, and all sales were at that figure. The Quotation Committee, however, declared the market firm at 20 cents. The sales reported were as follows:

Factory.	*Pounds.*	*Price.*
Darinda	3,000	21c.
McConnell	1,260	21c.
Red Clover	3,600	21c.
Total	7,860	

The sales for the corresponding week of the three preceding years were as follows:

Aug. 29, '98, 8,580 lbs. of butter sold at 18c.
Aug. 30, '97, 3,900 lbs. of butter sold at 18c.
Aug. 31, '96, 29,580 lbs. butter sold at 16@17c.

The New York market, Monday, was reported steady at 21 cents. H. C. B.

Elgin, Ill., Aug. 28, 1899.

DAIRY MARKETS.

choice, 9¼@9¾c; Young Americas, 9¾@10c; Swiss, 8@10½c; Limburger, 7@8½c; Brick, 8@9¾c.

Eggs—Fresh, at mark, cases returned, sold at 10½@11c; loss off, cases returned, 12½c.

Bran—Firmer and prices 25c higher. Offerings light and trading confined to one car at $11.25 per ton.

Cattle—The choicest beeves sold as high as any time this year, but the general cattle market ruled weak to 10c lower for natives, with instances of 15c decline late in the day. Seven loads of 1,449@1,513 .lb. steers sold at 6.60, some 1,518-lb. corn-fed westerns selling at that price; about a dozen loads averaging 1,400@1,540 lbs. sold at 6.40@6.50; most of the 1,160@1,380-lb. steers sold at 5.35@6. Comparatively few natives sold below 4.50. The 4,500 grass westerns received sold at steady prices, principally at 4.25@4.60 for steers and 3.20@4.45 for cows and heifers. Over 500 thin grass Texas steers sold at 3.45@3.50, averaging 895@906 lbs. Texas cows sold at 2.70@3.10; feeding cattle were in good request at steady prices. Country dealers took a good many grass westerns at 4.40@4.75. Native butcher stock steady.

FOND DU LAC, Wis., Aug. 28—Offerings 744 Twins and 550 Daisies; market quiet for Twins at 10c.

PLYMOUTH, Wis,, Aug. 22—Cheese—The sales reported today were 1,200 Twins at 9¼c; 250 cases Young Americas at 9⅝c, and 75 cases at 9¾c.

SEYMOUR, Wis., Aug, 22—Cheese—The offerings today were 318 boxes of Twins, and 173 Daisies; 248 Twins sold at 9⅛c, 74 at 9⅜c delivered at Appleton. 172 Daisies at 9⅜c.

MUSCODA, Wis. Aug. 28—Offerings to-day 1,200 colored Twins, 105 White Twins; market active; car lots 10c; local lots 9⅞c.

SHEBOYGAN FALLS, Wis., Aug. 23.—Sixteen factories offered 1,162 boxes of cheese on the call board today, and all except one lot was sold as follows: 377 cases Young Americas at 10c; 265 at 9⅞c; 106 Twins at 9⅝c; 50 at 9⅜c; 100 Daisies at 10c; 184 at 9⅞c, and 30 at 9¾c; market active.

NEW YORK, Aug. 28—Butter—Creamery, western extra, 21c; firsts, 20c; state extras, 20½@21c; firsts, 19@20c.

Cheese—State, full cream, large colored, fancy, 10¾c; white, 10c; small colored , 10¾c; white, 10½c.

Eggs—State, Pennsylvania and Western, 17@18c.

BOONEVILLE, N. Y., Aug. 21—Cheese—No sales of cheese were reported, but 9½c was paid for some, while others were sold on the basis of the Utica market.

OGDENSBURG, N. Y., Aug. 21—Cheese—1,277 boxes of cheese were offered. A bid of 9¾c resulted in no sales, but later on the street sales at 9⅝c were reported.

WATERTOWN, N. Y., Aug. 21—Cheese—On the Board there were no sales. On the curb the transactions were: 1,840 boxes at 9¾c, 425 boxes at 9⅝c: and 300 boxes and 60 Twins at 9⅞c.

NORWICH, N. Y., Aug. 21,—Cheese—The sales of cheese were: 460 boxes of large colored at 10c, 450 boxes of small colored at 10c, 187 boxes of small white at 9¾c, 600 boxes Skims at 8@8¾c.

LITTLE FALLS, N. Y., Aug. 21—Cheese—The extremely hot weather appears to have had a depressing effect. Nearly all of the cheese sold here today will go into cold storage. The transactions aggregated 99 lots or 6,098 boxes at 9¾@10c, the bulk being small white and small colored at 9½c.

Butter—There were sales here today of 26 pckgs of dairy butter at 18½@20c, bulk at 19c.

UTICA. N. Y., Aug. 21—The cheese market today showed a substantial advance in prices over those of last week, in sympathy with the firm tone at other primary markets and at the seaboard. Another cause of strength in the market, was the decided shrinkage in the make of cheese, because of the dry weather. Following is a list of sales: Lots, 192; boxes 14,193; prices, 9½@10½c.

The transactions on Aug. 23, 1897, were 8,601 boxes with the ruling price 8¾. The transactions on August 22, 1898 were 7480 boxes, with the ruling price 7c.

The sales of butter to-day were 19 packages at 20c; 26 packages at 20¾c, and 181 packages at 21c. Prints are selling at from 22@23c.

BOSTON, Aug. 28—Butter—Creamery extra, 21½c; western extra 20c; dairy extra 18@19c: imitation creamery 15@16c; western ladle, 14@15c; print creamery,22c; box creamery, 21c,

Eggs—fancy, near by, 17c; choice, fresh, 17c; Michigan extra, 16c; western, 16c; fair to good, 15c.

ST, LOUIS, Mo., Aug. 28—Butter—firm; creamery, 17@21c; dairy, 13@17½c.

Eggs—easier; 12c.

KANSAS CITY, Mo., Aug. 28—Butter—creamery, 17@19c; dairy, 15c.

Eggs—fresh, 11½c.

CINCINNATI, O., Aug. 28—Butter—firm, 21c.

Eggs—quiet, 11½c.

Cheese—firm; good to prime Ohio flat, 9c.

NEWARK, N. J., Aug. 28—Fancy Elgin creamery 21c, Receipts, fair.

PHILADELPHIA, Pa., Aug. 28—Butter—Solid-packed separator, creamery, extras, 21c; firsts, 20c; seconds, 17@19c; imitation creamery, extras, 17c; firsts, 15c; seconds, 14c; ladle packed, extras, 15c; firsts, 14½c; seconds, 13½c. Print butter—Creamery extras, 21c; firsts, 20c; seconds, 19@20c.

Eggs—Pennsylvania and nearby, 16½c; western 16½c; southwestern, 15c; southwestern, 12@13c.

BALTIMORE, Md., Aug. 28—Butter—Market steady; creamery separator, extra, 22c; extra first, 20@21c; creamery first, 19@20c; creamery, imitation extra, 17@18c; ladle extra, 16c; western store packed, 12½@13c.

Eggs—Market firm; strictly fresh stock, 14½@15c.

NEW YORK MARKET.

NEW YORK, August 26—Butter—Receipts for the week, 36,936 packages. Exports for the week, 6,493 packages.

The market is about same as last week, with perhaps a larger accumulation of fresh creamery makes, and receivers showing a trifle more disposition to meet the views of buyers.

Local trade confined their wants to extra quality only, and were obliged to pay 21c, but out of town buyers were able to buy lines of fine fresh creamery at 20c, and there is considerable stock of this kind going over unsold. Exporters bought very little creamery this week and took only finest lines at 20c; they are reported as buying considerable lines of fine June ladles at 15½@16c, and current makes at 14@15c. The supply of fine dairy is very light and the inquiry good, sales are readily made at quotations. We quote:

Creamery, extra 21c; medium, 19½@20c; poor 16@17c; Dairy, extra, 19@20c; medium, 17@18c; poor, 14@16c. Ladle, extra, 15½@16c; medium, 14½@15c; poor 13@14c.

Cheese—Receipts for the week, 31,525 boxes. Exports for the week 6,350 boxes.

The market continues to advance and the whole trade is wondering when prices will come to a halt. Sales in the interior are fully as high as here, and the demand seems to be general. Exporters bought large colored cheese at 10¾@10½c and small sizes sold readily to home trade at 10½@10¾c. White cheese are selling at ¼c pound under colored. Market closes firm. We quote:

Full cream, small, extra, 10¾c; medium, 10@10½c; poor, 7@9c. Full cream large, extra, 10½@10¾; medium, 10@10¼; poor, 6@8c.

Eggs—Receipts for the week, 54,049 cases.

Receipts were larger but the amount of fresh stock was only barely enough to supply the demand. We quote:

N. Y. & Pennsylvania, strictly fresh laid, per dozen, 19@20c. Northern & Western, strictly fresh laid, 16@16½c. Other sections, fair to good marks, 12½@15c. DAVID W. LEWIS & CO.
177 Chambers St.

BALTIMORE MARKET.

BALTIMORE Aug. 24—Butter—The receipts of separator creamery direct from the primary points have been of the usual quantity, since our last issue, and as a general thing the grading has been up to the expectations of the receivers, and it is suspected that in this opinion the buyers share, because the differences between them have been largely confined to questions of values; and as this has been "sellers" week, it is needless to add that the victory has been theirs, and at the close the advance has been general, and well sustained with every prospect of being permanent; probably some parcels may be carried over, but it is thought that this is because the retailers have not adjusted their prices to the new conditions, and are trying to do with a lower grade of goods. With gathered cream makes, there is this difference, that the quanity shipped from regular sources has shrunken about thirty per cent, since the flush of the season, and the quality has fallen away about the same proportion, and yet it seems to go into present use about as fast as received, many buyers having given up the higher grade that was available to them when prices were lower during the flush of receipts, and gone back to this useful variety. Imitation creamery and ladles are in light receipt, and good demand when fit for table purposes; the lowest grades are in fair demand also. Blocks and prints are not active in proportion to other styles of the same grades, because of so many absentees, who usually take these varieties. In storepacked the demand is good, receipts light; quality poor.

Creamery Separator, extras, 20½@21c; firsts, 19½@20c; seconds, 18@19c. Gathered Cream, extras, 18½@19c; firsts, 17@18c; seconds, 16c. Ohio, extras, 18⅝@19c; firsts, 17@18c; seconds, 16c. Imitation, extra, 16@17c; firsts, 15c; seconds, 14c. Iowa & N. W. Ladle, extras, 15c; firsts. 14c; seconds, 13c. Ohio & Indiana Ladle, extras, 15c; firsts, 14c; seconds, 13c. Ohio storepacked, extras, 12½@13c; firsts, 12c. W. Va., extras, 12½@13c; firsts, 12c. Creamery Blocks (2 lbs.) extras, 23c; firsts, 22c; seconds, 21c. Creamery Prints, (½ lb.) extras, 23c: firts, 22c; seconds, 21c. Md. Va. & Penn. Prints, extras, 19@20c; firsts, 18c; seconds, 16½@17c.

Cheese—Receipts of cheese continue light; demanp good; market firm as quoted.

New York State Cheddars, fine, 10¾@10½c; choice, 9¾@10c; fair, 8¾@9c. Fla s, fine, 10½@10¾c; choice, 10@10¼e; fair, 9@9½c. Small, fine, 10¾@11c; choice, 10¼@10½c; fair, 9¾@10c. Ohio Flats, fine, 9¾@10c; choice. 9¼@9½c; fair, 8¾@9c. Picnic, fine, 10@10¼c; choice, 9½@9¾c; fair, 9@9¼c. Swiss Cheese, fine, 12@ 3c; choice, 11@11½c; fair, 10@10¼c.

Eggs—Our egg market rules steady under continued light receipts of choice fresh stock; all receipts of this kind meet with quick sale at 14½c Heated and inferior stock are pressed for sale at irregular prices. G. M. LAMB & BROS.
301 Exchange Place.

MANCHESTER, ENGLAND, MARKET.

Copenhagen reports:—"A continued, very strong market with heavy over prices paying, and orders exceeding supplies by a long way. Quotation is expected other four kroner up to-morror. How long the trade can stand these advances we don't know, but apparently there is an actual shortness of butter, and the high prices are a natural effect thereof." The official rate is now definitely wired four kroner higher. At Manchester, notwithstanding the rise of last week, which it was feared would check the demand, there was again a good clearing demand for all choicest butters, which were promptly sold at our quotations. Secondary was slow of sale. The weather, which was cooler, has again turned warm. New York reports a shrinkage in receipts of ten per cent on the week, but from causes natural to the season of the year—warmer weather, drier pastures in some sections, flies, etc.—and was fully anticipated. Shipments to Europe since May 1st, are 34,006 packages, compared with 26,416 packages for the same period last year. A 30s rate of freight from New York by the Cunard and White Star lines, has been a strong inducement to shippers. Freights will be 40s this week, and accommodations first-class, so exports are expected to be as large as last week. The importance of the outlet cannot be over estimated, as American exporters hold large stocks of June and July goods, and are most anxious to export all August surplus to Europe. Of Danish and Sweedish, 19,702 casks are crossing for next week, being 239 casks less, and 1689 Finish, or 22 less. Cork market closes higher to-day for Irish, with an active demand and weather warmer. An increasing demand for margarines and mixtures is now manifest.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Wanted—An honest and reliable man capable of managing a large dairy. Must be experienced in all dairy work and with all dairy machinery. Liberal wages to good man. G. C. STREET Houston, Texas.

Wanted—A man to take charge of a creamery on shares. Seventy miles from Pittsburg. Address, CREAMERY, Hanoverton, Ohio.

Wanted—Married man and wife. Man must be thoroughly experienced in care, feeding and milking of high class Jersey cows and other stock, must understand separator and Babcock test. Woman must take charge of cream and dairy utensils and make butter. Must board themselves. Address BOX 173, North Greenfield, Wis. 29-2

1899 the Greatest of "Alpha" Disc Years.

For eight years past every year has been an "Alpha" disc year in the sale of cream separators, their success being greater from year to year and greatest of all in 1899.

Beginning with a relatively small sale in 1890 the superiority of the "Alpha" disc system was so great as to achieve instant success. The sale in 1891 was double that of 1890, and the sale of "Alpha" disc machines has thus continued to virtually double itself from year to year, in the Factory and Dairy sizes combined.

The recognized supremacy of the "Alpha" disc system is now so great in Factory separators that the purchase of De Laval machines in 1899 has been almost universal, exceeding 95 per cent. of the total sales in the West, and 85 per cent in the East. In the Farm or Dairy sizes of machines the users of such separators have not yet come to so well understand the differences between separators, but are rapidly acquiring this knowledge from practical experience, and the same percentages nearly hold good, and within another year or two will undoubtedly do so.

Users of separators—whether big or little—have come to understand that **The "Alpha" Discs are literally the heart and soul of a perfect cream separator** and that the all around efficiency and general practicability of the "Alpha" disc machine is simply unapproachable by anything else that can be put together in the shape of a cream separator, regardless of price, clap-trap claims of would-be competitors and every other conceivable consideration.

The differences in principle and construction between the "Alpha" and other separators are fully illustrated and made plain to every one in the De Laval catalogues—Creamery or Dairy—which may be readily had for the asking.

The De Laval Separator Company,

WESTERN OFFICES: Randolph & Canal Sts., CHICAGO.
GENERAL OFFICES: 74 Cortlandt Street, NEW YORK.
BRANCH OFFICES: 1102 Arch Street, PHILADELPHIA.

Wanted—Active young man to work on farm and in milk dairy. Must be good milker and able to manage retail route. Permanent place for right man. References required. W. W. McMAHAN, Eaton, Ind.

For Sale—25 choice milch cows, 3 to 9 years of age, and 15 heifers aged from 15 to 20 months, all high grade Guernseys. Also a full-blood Guernsey bull 2 years old for sale. A. L. STRONG, Elkorn, Wis. 29-2

Wanted—Position by an experienced buttermaker. A. R. EPPERSON, Frankfort, N. Y.

Wanted—to hire a good substantial and reliable farm hand. Middle aged and single. J. B. SHATTUCK, Cherry Creek, N. Y. 28-3

Wanted—By Sept. 1st, a single man to feed and look after a large herd of dairy cows in Colorado. Must be thoroughly experienced and a good milker. Steady place to right man. Address, giving full particulars and experience, BOX 524, Denver, Col.

Wanted—Man to take charge of Jersey dairy farm. Prefer a married man from dairy school. Must be well recommended and a worker. I do the kid glove part. State wages. GEO. A. BUCKSTAFF, Oshkosh, Wis. 29-2

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada 32-52

Married man, 30 years old, without children, wants position on dairy or stock farm to take management or otherwise. If necessary can run separator and make excellent butter. HENRY NIELSON, Box 56, Breese, Ill.

Wanted—A competent person, with about $1,500, to buy an interest in and run an established dairy, adjoining the city of Baird, Texas. Interest to be only in live stock and dairy outfit and not in the land, of which there is 1000 acres, 200 acres in cultivation and 800 acres pasture, all of which will be rented reasonably. All improvements necessary for first-class dairy. Spring, spring-house, 400-ton silo, barns, corrals, etc. Regular sale for creamery butter, 25c year round; milk 20c per gal. No other dairy. Address at once. W. C. POWELL, Baird, Tex. 29-3

For Sale—An almost new 16 inch Ohio feed cutter with 22 foot carrier. Used 10 days filing silo. Price $62 for outfit. Only reason for selling is we have a larger one of same make GEO. C. HILL & SON, Rosendale, Wis. 29-2

Auction of Guernsey cattle on Sept. 20th, on farm of GEO. D. TELFER, near Fort Atkinson, Wis. Watch this column for more extended notice. 28-2

Wanted—A thoroughly competent and experienced man to work a dairy farm. Must understand care and feeding of dairy cows. Also must understand steam and care of separator and all modern dairy utensils. Graduate of some dairy school perferred. For particulars address A. J. DAUGHERTY, Streator, Ill. 29-tf

Wanted—Two married men of small family, to work on dairy farm Must be sober, willing and industrious and thorough milkers. Men whose wives will milk, perferred. Steady employment to right parties. Must board themselves. Address P. O. Box 173, North Greenfield, Wis. 29-2

Wanted—An able bodied man and wife to work on and have charge of a stock and dairy farm. Address "A. B. C.," General Delivery, Quincy, Ill. 28-2

A Bargain—Ten head of registered Holstein-Friesian cows, butter bred and tuberculin tested. Price, $700.00. For particulars write L. C. MORSE, Sparta, Wis. 28-2

Wanted—Hand separator, second hand. State make, capacity and price. PHILIP W. FARR, Hamshire, Jefferson Co., Tex.

Very Low Rates to National Encampment, G. A. R. Philadelphia, Pa., Sept. 4 to 9, 1899, via the North-Western Line, from all stations, excursion tickets to be sold to Philadelphia, Pa., September 1, 2 and 3, only for trains arriving at Chicago September 1 to 4, inclusive. Apply to agents for full particulars. 28-2

Excursion Tickets to County Fair at Rockford, Ill.,—Via the North-Western Line, will be sold at reduced rates, September 2 to 8, inclusive, limited to September 9. Apply to agents Chicago & North-Western R'y.

Half Rates to State Fair at Milwaukee, Via the North-Western Line. Excursion tickets will be sold from all stations in Wisconsin and Michigan, September 9 to 15, inclusive, limited to September 16, at one fare for the round trip. Apply to agents Chicago & North-Western R'y. 29-2

Excursion Tickets to County Fair at Belvidere, Ill.—The North-Western Line will sell excursion tickets at reduced rates, September 4 to 8, inclusive, limited to September 9. Apply to agents Chicago & North-Western R'y.

For Agricultural Fair at Evansville, Wis., the North-Western Line, will sell excursion tickets at reduced rates, September 4 to 8, inclusive, limited to September 9, inclusive. Apply to agents Chicago & North-Western R'y.

Excursion Tickets to Milwaukee Industrial Exposition to be held September 2 to October 7, Via the North-Western Line, will be sold at reduced rates. For rates, dates of sale, limits, etc., apply to agents Chicago & North-Western R'y. 29-sp

To California, via the Midland Route.—Every Friday night, at 10:35 p. m., a through Tourist Car for San Francisco, carrying first and second-class passengers, leaves the Chicago, Milwaukee & St Paul Railway Union Passenger Station, Chicago, via Omaha, Colorado Springs and Salt Lake City (with stop-over privileges at Salt Lake City), for all points in Colorado, Utah, Nevada and California. The Tourist Car berth rate from Chicago to San Francisco is only $6.00, and the sleeping car berths should be reserved a few days in advance of departure of train. Through tickets and sleeping car accommodations can be secured from any agent in the east, or by applying at the Chicago, Milwaukee & St Paul Depot or City Ticket Offices in Chicago. Send for our free illustrated California folders. Address Geo. H. Heafford, General Passenger Agent, Chicago, Ill. 29-sp

Exceptionally Low Rates to Denver, Colorado Springs and Pueblo, Via the North-Western Line. Excursion tickets will be sold at greatly reduced rates from all stations, September 5, 6 and 7, limited to September 30, 1899, inclusive, account of annual meeting of Order of Hoo Hoo. Variable routes, delightful scenery Excursion tickets at favorable rates will be sold from these Colorado points to Ogden and Salt Lake City, Utah. Apply to agents Chicago & North-Western R'y.

Wise Policies Needed for Guidance.—Economy in Expenditures and Investment of Capital Necessary.—Practical Conditions Must Decide Crops and Selection of Breeds.—The Ayrshires as Dairy Cows.

ED. HOARD'S DAIRYMAN:—As years roll by the competitive struggle for existence does not appear to become more easy. The farmer's lot may not be the hardest, but it is not easy. Probably he enjoys as much of the blessings of existence as the followers of any vocation,on an average, and accumulates as much; although the opportunities for great acquisitions by the few, do not exist in a pursuit which is fitted for the many to pursue.

Reasonable success comes to more farmers than to any other class of workers. Nevertheless, the law of the survival of the fittest, and the influence of environment are in force among farmers as well as among lawyers, doctor, and merchants. Compare the situation of the cotton farmer of the south and the cow farmer of the north.

The farmers of our rough New Hampshire hill district have had a very hard and discouraging time of it since the opening of the comparatively near, fertile and easily tilled lands of the middle west. The established beef raising industry was made, and is now, practically, impossible in competition with easily tilled, rich corn lands. It is no wonder that a great part of the best blood of the district, left it for the west or for vocations in the towns. But now that the middle west, including Texas grazing districts, has skimmed the first cream of their lands, and has had to come down to the cow and general farming, it becomes apparent that there is just as good a chance for the farmer in these hills as anywhere.

Farms can be bought for a quarter part of the costs of improvements. The right kind of farming will extract the inexhaustible stores of potash and phosphoric acid in these naturally rich, though rocky soils. A beautiful country, near at hand and excellent markets, schools and intelligent society, and a marvelously healthful and vitalizing climate, more than counterbalances advantages of other and distant sections of the country. But to win success, the farmer has got to calculate very closely.

The issue of HOARD'S DAIRYMAN of July 28th, was of exceeding interest to me, because it touched on those problems of policy which have got to be solved and accepted before our local farmers can hope for success. One advantage possessed by the farmer is, that there is usually little need of his paying out ready money. What he raises with his own labor, he makes. If he improves his farm without cash expenditure, that is so much saved and laid away. If he does not make much, he does not risk a loss. I doubt if there is any farmer in the land who can make for himself the maximum rate of wages of his district in raising cow feed, if he depends solely on the butter or milk product of his cows for his returns.

A few able men, "drivers," can secure labor at a lower rate, and work it to a profit; but not the average farmer. The farmer who ventures outside of a safe conservatism in expenditures, stands a right-smart chance to lose more than he gains. The butter farmers of our district cannot afford to pay out money for cow feed of any kind, concentrated or otherwise. The importance of feeding a balanced ration is great; but if to balance the ration, one has to pay out more than is gained, where is the sense of such a policy?

There are some who think the fertilizing value of the boughten concentrates is a large item, but I think that value has been largely over estimated from a practical point of view. Farms can now be bought all over this country at a small fraction of the cost of creating the available plant food in them, through the process of buying concentrated cattle foods for butter making. Those who sell milk may afford to buy these foods, because they have got to pay out cash for the return of the fertility continually going off of the farm in the milk can; but the butter maker can do better by buying fertilizers to grow the crops he needs for feed.

The farmers of our section with its cool, short summer, have got to buy a soluble, concentrated fertilizer to drill in close to his corn seed, in order to secure a quick, early growth, if he is going to get a satisfactory crop. I am inclined to think that an investment in fertilizers for growing other forage crops would pay some sort of a return on any farm lacking in available plant food, if the manure is carefully saved and used in growing these forage crops; but for our local farmers, if they want to invest capital in their farms, there is no such other good investment, as in buying a good superphosphate to increase their corn crop.

The next best investment in fertilizers in my opinion is the purchase of wood ashes, for its effect in increasing the clover and other nitrogen collecting crops. How far it may be practical for our farmers to go outside of ordinary clover in growiug protein foods remains to be proved. But if it shall be decided that corn, clover, oats and timothy are the only forage plants that our farmers can profitably raise, (for, so far as I know, all the legumes are difficult to harvest and somewhat expensive to raise,) then will come up the question as to what breed of cows will most profitably consume and utilize these crops.

Many readers should be very thankful for Mr. C. C. Morris' paper on forage crops. It was helpfully suggestive. If a farmer cannot afford to give or buy a completely balanced feed for his cows, then it would seem that a breed like the Ayrshire would be more profitable than a breed whose one point is a large butter test. A ration having a disproportionate ratio of hydrocarbons would be somewhat more wasted if fed to a Jersey than to a cow who might need more of the hydrocarbon for her sustenance and ultimately produce more veal and beef than the Jersey.

No one claims that any one cow can be a great producer of butter and cheese and also of veal and beef, but the matter is still unsettled as to which kind of a dairy cow will bring in the most profit for the farmer's labor, a general-purpose cow like the Ayrshire or a highly specialized cow like the Jersey. The answer must largely depend on the price of butter. If there are enough pure bred Ayrshire herds in the United States and Canada that are capable of making a good show at the pail and that could be depended on for sufficient fresh and unrelated blood to warrant a farmer taking up this breed, there ought to be very many farmers who would be glad to know the fact.

There are innumerable farmers in the land who would prefer to keep a cow that would be of moderate value for milk selling, cheese making or butter production, and for veal and beef, than to keep the one-string-to-the-bow, highly productive butter cow. That may be a wrong policy to accept, but is it not time for the farmers of the country to call a halt and severely question the wisdom of the policy of putting so much effort into increasing the individual product of the cow? May not such extraordinary outputs be only secured at an unprofitable cost, in comparison with a more moderate yield from a larger number of cows, fed on a less concentrated and not entirely balanced diet?

Will Ayrshires or Jerseys pay best? Other things being equal, the cow whose organs of milk production are least taxed, will have the best general health and live longest. Special excellencies are always secured at a cost of defects in other characteristics.

I have been re-reading Flint's "Milch Cows and Dairy Farming." Thirty years ago this work was law and gospel relating to dairy matters. The author in those days did not know the silo and the centrifugal separator. He thought the proportion of butter and cheese in milk was largely regulated by the quality of the feed, but most of his teachings are as good today as then. The scientifically balanced ration table was not in existence then, but good dairy farmers knew that linseed, cotton seed and bean meals would increase the flow of milk.

Flint rated the Jersey cow as being first-class for the gentleman's lawn, and rated the Ayrshire as being the best and most profitable all around dairy cow. Why has the Ayrshire receded into the background? Is it merely a matter of fashion? Of course, the intensive butter cow is the cow for the butter specialist, but fine butter is cheap now and if all the farmers in the land get good silos, raise balanced rations and grow from pure bred Jerseys or high grades, where will the price of butter go to? Is it not rather a risky thing for a whole district to take up a purely specialized butter cow? If there are good Ayrshires in existence, why not hear from them? I had one many years ago that was a grand cow in every respect. She cost $100 and was well worth that money in those days. J. M. W. KITCHEN, M. D.

New Hampshire.

Dairying in South Dakota—Running Separator with Water Power.

ED. HOARD'S DAIRYMAN:—For benefit of C. J., Aug. 11, HOARD'S DAIRYMAN:—I have been running a No. 2 Baby separator with water power for about three years, and find it very satisfactory. Get supply of water from small artesian well, flowing about one barrel per minute. For a resevoir I use a 100 barrel tank. I made an overshot water wheel, nine feet in diameter, with galvanized iron buckets and spokes,something like a bicycle wheel. The tank is elevated four feet, and the wheel in pit, five feet; the waste water runs off through a drain.

The tank furnishes a two foot head; 1½ inch stream from tank gives sufficient power, and with what well flows will run separator one hour.

We use this power for churning and last year made nearly 7,500 pounds of butter; it makes a very nice power as it is always ready.

South Dakota is all right for dairying, land is cheap and grass and hay and corn fodder make good feed with grain. We have to pay from $5 to $7 per ton for bran. I have only had three years' experience with dairying, but so far have found it very satisfactory.

I like to read the DAIRYMAN, as it gives me ideas to study on and helps me in mapping out my work for the future. I aim to make the dairy a specialty and am thankful for any suggestion that will improve my condition and plans.

My herd, last year, consisted of twenty-eight common cows, fresh about the first of September, and so they are now beginning to come fresh again. We shipped over 7,000 pounds of butter, which netted an average of 20 cents for the year. The calves raised are worth $500, and $200 for hogs sold which were raised mostly on grass, skim milk and buttermilk.

Feed was all raised on the farm except bran, which for the year, cost $150. In addition, we raised 2,000 bushels of wheat and all the oats and corn we fed. My cows are Short-horn grades, but as my aim is butter, I have placed at the head of my herd a young bull from Karlen & Co's herd, Valencia Sir Mechtchilde, and hope to produce a herd of cows that will beat the old ones.

If C. J. would like further information about water power and will write me direct, I will answer any inquiry. F. E. MOSES.

Emsby, S. Dak.

Night and Morning's Milk.—Using the Separator.

ED. HOARD'S DAIRYMAN:—I notice in your issue of Aug. 11th, an inquiry by F. I. Cowles, in regard to the relative yield of cream of morning and night's milk and the occasional difference in the quality of cream or volume,from a given amount of milk from the separator.

In regard to the first question, I will say that it seems to be an established fact that the morning's milk, even if the intervening period of time between the two milkings be the same, the morning's milk will be less in quantity, but test higher in fat, and even though less in quantity, will contain more fat on the whole than the night's milking.

The physiological reasons for this seem to be not very well understood generally as yet. Whether it be, as in the case of Mr. Cowles, the cows having a large pasture to range in during the day time and being confined in a small yard at night, it might thus be that the increased exertion and probably a larger

GOLDOMETOR for locating gold, silver and other minerals. In a pocket case. Also Rods and Spanish Needles. Catalogue, 2 cent stamp. B. G. STAUFFER, Dept. H. D., Harrisburg, Pa.

quantity of water drank during the day, account for the larger amount of milk and the lower test at night and on the whole less fat.

The cows being confined in a small yard at night, thus keeping them more at rest (quiet being made an essential feature in the successful care and management of the dairy cow), might have so beneficial action on the nervous system of the cows, that it will stimulate the system to the larger yield of fat.

In regard to the second question, I will say that the speed, feed and temperature are the three cardinal points to be observed in operating a separator. The speed of a separator determines to a large extent the quality of the cream, or relative yield or volume of cream to a given quantity of milk. If the speed of the separator goes up and the rate of inflow remains constant, the volume of cream will be decreased, whereas, if on the other hand, the speed goes down, the volume of cream will be increased, and consequently a thinner cream will be obtained.

The quality or volume of the cream may also be changed some by the rate of the inflow. If the speed remains constant and the inflow is decreased some, a smaller quantity of milk flowing into the bowl, it will remain longer in the bowl and be more exhaustively separated, i. e., a richer cream, or decreased volume for a given quantity of milk.

The temperature effects separation, inas much as a higher temperature will decrease the viscosity of milk and thus facilitate the separation of the fat globules from the milk serum. Ordinarily a temperature of 75° to 86-90° F., varying with the season of the year and period of lactation, will give the best results, but the efficiency of separation is increased with an increasing temperature, up to about 155° to 160° F. as a maximum limit.

It is possible to increase the flow of milk into the bowl, when a float is used and float capacity already established, by enlarging the opening into the bowl in the regulating cover and increasing the speed correspondingly, but this is generally not advisable, as it leads to over taxing the capacity of the separator. H. J. BERNARDS.

Bear Lake Co., Idaho.

Building a Grain Stack.

A grain stack should be started very much like a round shock. Care should be taken to have the stack round and to have the heart of the stack in the middle so as to induce even settling on all sides. The bundles on the bottom of the stack should all set on end, so that few heads may come in contact with the ground. After the bottom has been built out large enough it should be bridged over and the bundles laid flat. This method of laying the bundles should be followed until near the drawing in point. It is best to not try to keep the "butt" of the stack too steep, but to keep the heart full and the body of the stack, except the outside row, packed down very solid. While the "butt" of the stack is protected by the top and will not get wet, as a usual thing, it is quite important that it be well built and kept level and hard. If put up loose and carelessly the stack is very likely to swing over to one side in settling. The bundles do not lap quite one-half i. e., the butts of the bundles in the inner rows are laid three or four inches inside of the bands of the bundles below them. This will keep the stack about the right pitch until ready to draw in. If the stack becomes too flat at any time it can be steepened by laying the rows closer together, thus getting an extra row in a course.

DRAWING IN.

When the stack is high enough from the ground to "draw in" it should be steepened by laying a double course at the outside of the stack and by lapping the bundles clear to the bands. It is important that plenty of room be left at the outside of the stack between rows one and two, so that there will be little danger of slipping out. Rows two and three should be laid very close, row three leaving only three or four inches of row two uncovered. The balance of the rows to the center of the stack should be lapped to the bands. This method of laying the bundles should be followed as closely to the top of the stack as possible, thereby keeping the heart very full. It is wise to occasionally leave out the double row if the stack becomes too steep.

TOPPING.

Topping out a stack is rather the most difficult part of the process, though a nice, smooth top is not of so much importance as a good shoulder, by which is meant that part of the stack just above the "drawing in" point. If the center of the stack is kept full and solid all the way up, the few top bundles are not of so much consequence, as the top is narrow and will dry out if it does get wet. If a stack has a bad shoulder, however, and gets wet it is very difficult to dry it out, and usually the water will settle to the center in such a case. The stack should not be drawn in rapidly at the start as there will be a tendency to take in water at the shoulder unless left full and rounding. When near the top it can not be drawn in too fast so long as it is kept very full in the middle.

Nearly everyone has a way of his own for topping out grain stacks, so the only rule that will be given here is to keep the heads of every bundle pointed toward the center of the stack and to keep the center *full* enough, so that the last two or three courses may be drawn in very rapidby, leaving a round and rather short point on the stack. Finish by placing two or three well broken up bundles over a stake run six or eight inches into the top of the stack.

STACKING WITH A FORK

Is much preferable to stacking on hands and knees. When once accustomed to stacking with a fork a man can stack fully as fast as with his hands, and it is easier on both pitcher and stacker. In kneeing a stack it is necessary to get very close to the outside of the stack, even while drawing in. This is contrary to good principles in stacking, as the outside should be left loose that it may settle as much as the center.

In fork-stacking the stacker can keep near the center of the stack most of the time, and he should never get closer to the outside than the second row, thus leaving the outside loose and with plenty of room to settle. The harder he can tramp the center the better. A good sized bulge is also an aid to the proper settling of a stack. In short the end desired is to have the center hard and compact enough to settle but little and to have the outside loose and overhanging to allow of all the settling possible. This end is best accomplished by fork-stacking.—*Farm, Stock and Home.*

Butter as a Food.

A writer in the "*Vegetarian*" has the following: "It will first be well to make clear the difference between butters and other fats, and then to deal with the process of manufacture. The fats (butters) which are obtained from the secretions of the mammary glands of most animals are materially different in composition from those which occur in the adipose tissue, and it is in this difference chiefly that the superiority of butters over animal fat lies, for the butters that are intended for the tender digestions of the very young are, of course, much more readily acted upon by the pancreatic juice than are the fats obtained from the adipose tissue, and thus more readily assimilated by the system. Furthermore, milk fat, when taken in the form of milk or cream, is already broken into exceedingly fine particles, so that the process of digestion has thus partially been performed; for the digestion of oleaginous matter does not, as in the case of food of an albuminous or carbohydrate nature, consist so much in its decomposition by the gastric juice and the pepsins contained therein, but chiefly in its emulsification and its occlusion by the villi in the small intestines. Fats are also partly saponified by the pancreatic juice, and here again butter fat is much superior to any other, as being far more easily decomposed. So it is evident that, partly owing to its peculiar physical condition, and partly because its chemical constitution renders it more easy of digestion than any other fat. Where fat is required to retain the temperature of the body—as it is in considerable quantity in all the temperate climates—butter fat holds, par excellence, the first place.

Mottled Cheese.

In some seasons considerable trouble arises with what is known as "mottled" cheese. A cheese maker sent a small sample of mottled cheese to the college in the autumn of 1897. From this sample a starter was made by pasteurizing skim milk, and to this was added some mottled cheese, which has been finely grated. After the starter had developed properly, it was strained into a vat of 300 pounds of milk, on 27th November, 1897. The cheese made was very badly mottled, and had a characteristic unpleasant odor. On 1st December, 1898, the coloring had nearly all disappeared.

Further experiments were made during April, May, August and September, 1898—forty-five in all—300 pounds of milk being used in each vat. The cheeses were colored with Hansen's cheese coloring at the rate of one and one-fourth ounces per one thousand pounds of milk. In most cases a "control" vat of the same milk was used. Starters were made by pasteurizing skim milk and adding to it, either some of the cheese from which it was desired to make a starter, or some of a previous day's starter. On four days sour whey from the whey tank was added directly to the vat of milk. Several cultures, prepared from mottled cheese, were used as starters.

A complete record of each experiment is given in the report under review, but it will suffice here to give the main conclusion, which were arrived at by the experimenters:

1. Mottled cheese may spread from one day's make to another, but it is most likely to do so from or through the starter.

2. The mottles usually appeared in from two to four weeks after the cheese was made.

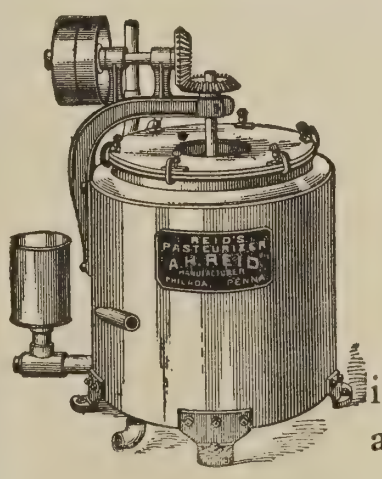
3. Sometimes a starter produced mottles, and some times the same starter did not.

4. Pasteurizing the whole milk used in the vat did not prevent mottling.

5. In no case did the mottles appear in the white (uncolored) cheese, made from any of the starters.

6. The cultures (made from mottled cheese) did not cause mottling to any extent. In one or two cases there was a slight waviness or mottling.

7. In some cases the mottles appeared quite strongly, and then disappeared after a time. In some cases the mottling appeared in spots through the cheese. A cheese made 22nd August, was examined on 29th November, and the first plug showed no mottles. Out of five plugs drawn from different parts of the cheese, two of them showed mottling.



8. Starters made from the whey tank produced mottling of the cheese and a very bad flavor. It is probable that the difficulty is caused in some cases by taking whey home in the milk cans and then sending the milk to the factory in these cans, not properly washed and scalded.

9. It is also probable that the root of the difficulty lies in the fact that a germ or bacterium attacks the coloring matter, added to the milk to produce colored cheese. It takes some time for the effects to become marked and the white spots to appear.

10. It is likely that the trouble appears only under certain favorable conditions of weather, etc. Should this trouble appear in a factory, the maker should look closely after the whey tank and washing of cans, especially if the whey is returned in the milk cans. He should also make white cheese, which are cleaner and more wholesome.—*Rep. Ontario Agri. Coll.*

That Grass or Garlic Taste

as well as all other tastes and odors are removed by the Reid Pasteurizer. The cream and butter always retain their fine flavor, keep sweet longer and sell at better prices than unpasteurized The

REID Pasteurizer

is the only practical, scientifically constructed, and economically operated pasteurizer built.

Mechanicsburg, Pa., Aug. 1, 1899.

We have used Reid Pasteurizers in each of our four Creameries for twelve months, and now cannot speak too highly of them. Is this sufficient recommendation? We would not be without them under any circumstances.

Yours truly,
THE CUMBERLAND VALLEY CREAMERY CO.

New York Farm and Dairy Notes.

Handling Ensilage Corn.

ED. HOARD'S DAIRYMAN:—The following plan of handling ensilage corn when it is put in the silo whole, as many farmers still do, and which has been sometimes practiced on our farm, may be of use to some of your readers. The only kind of corn we ever put in the silo without cutting with the ensilage cutter, was an early variety of flint corn, and this was planted so thinly and it eared so well that there was a heavier weight of ears than of stalks. The tall growing varieties of corn I would always run through the ensilage cutter. The corn is cut and laid in bunches, an armful in a bunch. In drawing the corn to the silo, two low-down wagons are used, on which are platforms of planks.

Before the corn is placed on the wagon, two lengths of rope, with the ends tied together, thus forming a loop at each end, are laid on the bottom of the wagon and lengthwise of it. The rope should be a few feet longer than the wagon. On this rope is placed a layer of corn, one or two feet deep, and then another rope is laid down as before, an another layer of corn put on, and so on until the load is completed.

It was then driven to the silo where the corn had to be elevated ten feet or more to the top of the silo. A large rope ran over pulleys at the top of the silo; at one end of the rope is attached a jointed hook, so made that when a load of corn is drawn up by it, it can be dumped with a rope attached to it. One end of the binding rope on the wagon is picked up, and pulled through the loop at the other end, and the hook is hooked into it. A horse hitched to the other end of the large rope, draws the bundle of corn to the top of the silo, where it is dumped in layers on the bottom.

By this plan there is no lifting of the corn when unloading, and large loads are unloaded in a few minutes. The only hard work is in cutting the corn and placing it on the wagon. With the use of the corn harvester this part of the work is made easier, and I suppose the corn harvester will soon be as generally used as the reaper or binder. I know by experience something about the hard work of lifting the heavy armfuls of green corn stalks, and the sore muscles and lame back resulting from a long day's work in the field, or in lifting the corn from the wagon, and carrying it to the top of the silo.

Of course this plan of unloading the corn is of no use to those who cut the stalks and use an elevator to carry them into the silo, but when the smaller varieties of corn are grown, having mature ears, I think the main advantage in cutting the corn is, that the work of taking it out of the silo is facilitated. We have not found this very difficult when feeding the uncut stalks, and the extra work certainly is not equal to the cost of running an ensilage cutter, if one has not the power of his own to drive it. I want ears on the stalks which are nearly mature, then if the corn is put in at the right time, the quality of the ensilage will be good.

When using the ensilage cutter and elevator, it may be that all of the readers are not familiar with the plan of using the tube made of sacking to facilitate the work of distributing the corn evenly over the bottom of the silo. This method has been several times described in the agricultural papers, but it may yet be new to some. Several of the large grain sacks are cut open at the bottom, and sown together so as to form a tube reaching from the top of the elevator to the bottom of the silo. The corn from the elevator drops in to the top of the tube, and as it falls to the bottom, a man takes hold of it and carrying it around the silo, thus distributes the corn evenly over the bottom of the silo. As the silo fills, the tube is shortened by removing one or more of the sacks. This is much easier than the old way I used to practice, of pitching the corn around the silo with a fork as it fell from the cutter.

With the help of the corn harvester, the low-down wagon—using two, so one wagon may be driven to the platform by the cutter and the corn put through the cutter as fast as unloaded, while the other wagon is loaded in the field—the elevator, and the tube for distributing the corn as described, the work of filling the silo need not be hard, when the stalks are so large they must be run through the ensilage cutter. After the corn has been cut in the field, five men will be needed to keep the ensilage cutter running, and two teams, if the corn is cut by horse power as we usually have done on our farm; one man to load the corn in the field, one to drive the team, one to unload it, one to feed the cutter, and one man in the silo. If an engine, or other power is used for driving the cutter, only one team will be needed.

In my locality the gasoline engine is sometimes used for cutting corn, and I think very satisfactorily. Where the farmer keeps two teams, or can change work with a neighbor, probably the tread horse power is the most economical for cutting the corn. When many acres of corn are grown, and the business carried on on a large scale, the steam engine will be needed to drive the cutter. Farmers would do well to keep an account of the exact cost per ton of filling the silo. One enterprising farmer in my neighborhood has found it has cost him thirty cents per ton to store the corn when it was grown ready for the silo, and I think this about the usual cost of filling the silo in this vicinity. The most of the farmers, who have it, use buckwheat chaff for covering the silos when they are filled. W. J.

Delaware Co, N. Y.

Notes From Southern Pennsylvania.

ED. HOARD'S DAIRYMAN:—That is an excellent idea of calling attention to the best the paper contains—it is very helpful to us busy readers. Could not you make that a permanent feature. Sometimes we have time to read all the paper contains, but at others we are so pushed that we hardly have; but we do want to get at least the richest cream.

But I want to say I hope every reader will read every word on the editorial pages in every copy, as that contains more of the real kernel of dairy information and wisdom than all the other pages. This last for the readers, not for the editor.

DILUTION SEPARATORS.

Call them delusion separators and you come nearer the truth. Some one said farmers must have a lot of ready cash and the boom of good times have reached them, by the way they spend money for these fake cans. No, my friends, I know some of the buyers personally, and they take the money that they sorely need to buy clothing and food for the wife and children; they are simple folk and are simply *swindled* by a set of unrighteous, cussed rascals who are out of jail. One man who works hard, and his wife and children work like slaves, gave his note for $23 for a tin can worth possibly $2. I have no remedy to propose. Those people will not read any papers, they will not come to our farmers' institutes, and, frankly, I do not pity them, but I do pity their wives and children. I am afraid their case is hopeless.

THE VICIOUS BULL.

This topic should not be dropped from the dairy press. Dairymen and farmers become so reckless, that it is well to repeat danger signals. I see the *Breeders' Gazette* advises killing the vicious bull, but that is poor advice and cannot be followed. There may be extreme cases where such a course is advisable, but in general the advice is foolish. I think I am safe in saying that seven-eighths of all Jersey and Guernsey bulls at maturity, or four or five years of age, are more or less vicious. Sometimes they do not show much of this bad disposition in general, but all of a sudden they will become furious and kill some one.

Of this a few terrible examples have come under my observation lately, in this part of our state. In my own county, the Hon. Gerard C. Brown, one of the noblest sons of the State of Pennsylvania, was killed by a Guernsey bull who never showed much bad temper until he made the fatal attack.

A large bull should absolutely not be at liberty in the field or in the yard with the cows, though they may be in appearance ever so gentle, as they may in an unexpected moment become furious and do just what hundreds of their progenitors have done before.

It is very poor policy anyway to have the bull running with the cows and young stock, not to think of the risk, as we cannot keep a record and do not know when our cows should be dried off nor when they need the attention we should always give cows at calving time. Besides, the heifers will frequently come in too young. Keep the bull in a bull proof pen or stall and always use proper precaution whenever it is necessary to handle him. *Never trust a big bull.* This last sentence would save many lives annually, would every stockman heed and practice it.

OUR CORN CROP.

We have a very large corn crop maturing finely, but only a very few of our people are in a position to utilize the crop properly. But the leaven is doing its work slowly. Quite a number of parties have written or

4,000 Pounds
is the guaranteed capacity of this wagon. It is equipped with
ELECTRIC STEEL WHEELS
with stagger oval spokes, broad tires, etc. It has angle steel hounds front and rear. It's low down and easy to load. One man can load it; saves an extra hand in hauling corn fodder, etc. A pair of these wheels will make a new wagon out of your old one. Send for free catalogue and prices.

Butter Bred Bull Calf, 10 MOS. OLD, a Little White.
Very handsome . . . Send For Pedigree. **$50.** J. P. BRADBURY Pomeroy, Ohio.

called to get definite plans for silos and I am glad to say in most cases they are readers of the DAIRYMAN. The others move along in the rut, in blissful ignorance.

The crop of corn stalks is too valuable to neglect, even though you have not yet a silo. By careful management the crop of stalks can be made very valuable as a winter feed. Care for it just as you do for your choicest hay and it will be all right.

A number of our experiment stations have determined that the feeding value of the stalks on an acre is about as much as that of the ears, and every one of us who has fed nice, well cured corn stover to milk cows, knows that ton for ton the stover is to be preferred to well matured timothy hay.

Now, look at the prices of hay. I see in our Baltimore market, at the hay scales, it is quoted at $15, while hay buyers are out offering farmers $11 per ton in the barn, for choice. Can we afford to waste a feed so valuable? We can not get $15 per ton for our stover, but if we cut, cure and store it in the best possible condition, it will take the place of hay, which in the end amounts to the same thing.

In the large corn fields of the west, cutting machinery will no doubt pay, while we in the east with our rather small acres can more generally cut it cheapest and most satisfactory by hand. The shredder or fodder cutter is of course an absolute necessity for every one who desires to most economically utilize the corn plant.

THAT SKIM MILK VAT.

The worst abomination about the creamery, especially at this time of the year, is that large vat into which the skim milk is run and from which the patrons help themselves. It is sometimes cleaned out. Not long ago a friend informed me that when they reached bottom in theirs they were astonished to find a dead dog. That is the worst case I have heard of yet thus far, but the only wonder is that any hogs can drink such abominable stuff and live. Then think of putting such stuff into the cans to be used to-morrow to bring milk from which to make good butter. Patrons and creamerymen should combine to abolish that vat. The milk should be taken as it comes from the separator and not allowed to rot before it is fed.

L. W. LIGHTY.

Adams Co., Pa.

Cream for Whipping.

Separator Cream Will Not Whip as Well as Hand Skimmed.

ED. HOARD'S DAIRYMAN:—In answer to your favored request to give some light upon the above point, as claimed by a subscriber in Missouri, I shall try to do my best, though I fear I cannot give full satisfaction.

The claim is an old one, and many parties yet stick to it, and some actually yet prefer a hand skimmed cream for that reason. Still I have found a great change going on in favor of the separator cream. The large city ice-cream manufacturers were slow in admitting, that taking every thing into consideration, they were better off with the apparently thinner, more fluid cream from the separator, which could be depended upon as absolutely sweet, than with thicker, though not actually richer, cream gained by the old-fashioned method of skimming by hand, after setting the milk, warm from the cow, in shallow pans for twenty-four hours or longer.

I mention this most old-fashioned way, especially, because the same objection, which at first prevailed against the separator cream, also held sway quite a while as to cream gained from "Cooley creamers" or by any manner of "deep setting" in ice-water, as compared with the "shallow setting" cream.

But, while, of course, the "deep cold" way was a great improvement over the "shallow lukewarm" method, still anyone who has gone deep enough in the subject knows now, that the separator was even a far greater step forward. And yet, I guess it must be admitted that some of the great whipping capacity of the old-fashioned cream has been lost.

All that is left for the producer and retailer to do, is to convince his customers as to the far more healthy character of separator cream, no matter whether used for coffee and tea, ice-cream, or whipping, than of cream which has been exposed to a surrounding air of very doubtful character for twenty-four hours. And while I myself only know too well, that it is of no use to make customers change their taste according to our convience, still it becomes a very different matter when we can get the physicians on our side, and positively be able to prove the enormous amount of bacterial life of every kind and description, which is to be found present in milk and cream thus exposed.

While, no doubt, a great majority of such germs may be harmless, still it is seen that many are not, and the apparent greater thickness of hand skimmed cream of only 14%, as compared to fresh separator cream of 20% or even 24%, is really only caused by a beginning deterioration, which in a very short time will cause a most undersirable souring.

I am confident that in the long run, our customers will prefer to pay a little more for cream for whipping purposes, guaranteed to contain a higher fat per cent, when they find that in case part of such cream was not used at once, but was left over till next day, such cream would have just as sweet and fresh a flavor, as when first received.

If the same customer had bought the "thicker," hand-skimmed stuff (pardon the name), they would the next day have had some mean tasting, rank, probably sour stuff on hand, not fit for anything. And this is what causes the growing favor which pasteurized cream is gaining among the best class of city customers, that they have cream which is O. K. the day after it was bought, even in hot weather.

But your inquirer may say, this all is no solution of the problem in his case. I have one more suggestion to make, and while I never myself have tried the method, still I believe it might be made of practical value if properly applied. I refer to the

RESTORATION OF THE VISCOSITY OF CREAM,

as invented by Messrs. Babcock and Russell, of Madison, Wis. Of late several inquiries as to this method have appeared in HOARD'S DAIRYMAN, and the inquirers have been referred to the bulletin on that subject by the Wisconsin Experiment Station. But with all my regard for the ingenuity of the invention and its possible usefulness, still its dangers are so many that I have decided to let it alone.

The fact that the addition of any matter, in ever so small proportion and of a perfectly innocent character, is against the laws of many states and cities is an added reason for not using it. That "viscogen," properly used, will do all that is claimed for it, and give no offensive taste of lime either, is sure; still if not applied properly by the dealer, it is apt to do more harm than good. Therefore, I advise producer and dealer to let it strictly alone and not to tamper with anything whatever to be added to milk or cream.

But it would be quite a different thing if we could introduce "viscogen" in a form in which the customers and their cooks could use it and just add the amount necessary, given by directions, for the amount of cream which they either wish to whip or use for ice-cream. Then "viscogen" would be entirely legitimate and probably become even more popular than "Hansen's Rennet Tablets" for making "Junket" (clabbered sweet milk), which are now sold by most grocers. I, for one, wish that Dr. Babcock and Prof. Russell would try to find a way to make such a way for the use of "viscogen" possible, and then would be glad to supply all my customers upon demand.

Washington, D. C. J. MOLDENHAWER.

Keeping Hogs Healthy.

Mr. Niles, a veterinarian, in a paper read before the Iowa Swine Breeders, said:

In connection with the loss of young pigs I only wish to point out the fact that diseases of the young are on the increase, that several of these troubles, such as the troublesome ulcerative sore mouth, some form of diarrhœa the nasal disease, known as snuffles and some others, are infectious, and are due to some element in the yards, nests, etc., capable when it comes in contact with the pig of setting up a disease process. In dealing with all of these troubles, prevention should be the rule. Perfect cleanliness, with disinfection of pens with carbolic acid, chloronaptholeum, creolin, or some other equally good agent, and of the soil with lime, should be the means employed. The separation of the well from the sick is also an important feature. The most severe plague of all to the young pig is our old enemy—hog cholera. Our observations have convinced us of the fact that it is not safe to re-stock cholera yards and pens for at least one year after the disease has disappeared.

To place hogs in the spring, in yards where swine died in the fall, and up into the winter, with cholera, is very liable to develop another outbreak of the disease. In order, then, to most effectually rid the farm of the disease, new yards and pens should be provided for all uninfected, swine brought onto the farm. For the purpose of providing shelter in new yards, and for the ease with which it may be disinfected the small movable hog house is a most valuable factor in swine growing. It would be hard to say too much in its favor. For the accommodation of the brood sow and for a small lot of shoates it is especially well fitted. That water courses may be a factor in the spread of disease, should be kept in view. During cholera times water from a well is always preferable, and if possible the herd should be fenced away from the stream unless it originates on the farm. Whenever there is danger from cholera our herds should be as completely isolated as it is possible to make them. Especial pains should be taken to prevent, in any way, contact with outside hogs. Prevention is always better than a cure, and without disease germs be in some way brought to the herd the disease will not appear. Much complaint is heard throughout the country regarding the complications following castration. Just a brief hint concerning them.

As a rule pigs should be castrated early, but never when there is a probability that they will be exposed to cholera before recovering from the operation. At this time the pig is more liable to take the disease, the attack is more severe and recovery consequently less liable to occur. The knife used in performing the operation should always be surgically clean, that is, free from infection. This condition can be easily brought about by immersing it in boiling water for a few minutes. The openings should be made low down, and of sufficient length to insure good drainage. Should the objectionable bunches appear, which will seldom be the case if the operation be performed in this way, remove them early with the knife. When small they may be easily removed without danger to the pig, but if allowed to reach great size their removal becomes difficult and death often follows.

HOLSTEIN-FRIESIAN CATTLE

Owned by **JONES & RANDALL, Hustisford, Wis.** 100 head to select from. From families rich in butter fat. Herd now headed by Barron Paulina De Kol. Stock for sale. Prices reasonable.

HOME FARM HERD.

Headed by Jewel of Home Farm, Sweepstakes Holstein-Friesian Bull Trans-Mississippi Exposition Omaha, Neb. Seventy-five head to select from. **W. B. BARNEY & CO., Hampton, Iowa.**

MEADOW LAWN HERD Holstein-Friesians.

Herd headed by **Sir Brookside De Kol.** Choice young stock for sale. Come and see them. C. W. HARRISON, Ringwood, McHenry Co., Ill.

Holstein-Friesians

MECHTHILDE BULLS FOR SALE. Address **M. W. BARDEN,** Portage, Wis.

McGEOCH FARM Holstein-Friesians.

Herd headed by Gem Pietertje Hengerveld Paul De Kol and Johanna Paul Colantha. A few young bulls, 3 to 7 months old for sale at bargain prices. H. B. DAGGET, Mgr., Lake Mills, Wis

CAREME

Is the 4th highest butter cow in Holstein history. Her butter record is 35 lbs. 9 oz. in 7 days, 100 lbs. 12 oz. milk in 1 day, 2,591 lbs. in 30 days. Winner of first prize at New York State Fair, 1888. Breeders' Gazette says: "Greater things are expected of her than she has already done, she is hard after Mechtchilde." Valley Mead Farm boasts to contain the best of everything, so it possesses also three daughters of Careme, which have been great prize-winners, and many grand-daughters. VALLEY MEAD FARM, Monticello, Wis.

Markham Manor Farms. Simonsville P. O., Andover, Vt.

Holstein-Friesian cattle bred from the most fashionable butter families, individually large producers, and of the most approved show form. The herd contains seven daughters of Sir Netherland Soldene Clothilde, No. 18390, H. F. H. B., the most remarkable show bull of recent years. Also large English Berkshire Swine from noted prize winning and imported stock. Write for description and prices to **J. A. THORNTON,** Mgr., **Simonsville, Vt.**

130 Holsteins. First prize herd at Trans-Mississippi Exposition at Omaha. 1st and 2nd on aged cows and 1st, on two-year-old heifer in the seven day butter test, open to all breeds at same Exposition. Three cows in this herd have produced the most butter in seven days of any cows ever officially tested. A score of others nearly as good. Our richest bred bull calves are taken young. Sons of De Kol 2d and Netherland Hengerveld head the herd. Animals of both sex and any age for sale. Write stating just what you want. HENRY STEVENS & SONS, Lacona, Oswego Co., N. Y.

Corn Fodder and Milk Flow.—Water Supply and Shade in Pasture.—Creamery Sharks in New York.—Pure Blood vs. Scrubs.—Big Butter Yields.

ED. HOARD'S DAIRYMAN:—Everybody, agricultural editors and writers included, is praying for rain, while the cows are preying on everything within their reach, or beyond it, that has digestible nutrients in it.

Just why some of the farmers do not cut and feed their corn to their cows is a conundrum. With cheese selling at ten cents, one would naturally be led to think that it would be a good financial scheme to so provide for, and feed the cows, as to keep up their milk flow; but, as in years gone by, the farmers are caught in the lurch; no summer silos, and many of them without "sowed corn", even.

Meanwhile, in many pastures, the water supply is failing, while the horn-fly pest is greater than ever. No shade in many pastures; a red blazing sun; a 90° in the shade temperature, with only a scanty covering of November, brown colored grass in the pastures, furnishes a poor outlook for the cows on which the hopes of many a farmer in Northern New York depend for cash to pay accrued interest, or to make payments on that mortgage.

Last year at this time cheese sold for seven and one-half cents. Last Saturday it reached the ten cent notch, but the offerings were enough less to fully offset the difference, so that, to the farmer, who has no feed for his cows, the advance of two and one-half cents per pound for cheese brings no relief.

There are some farmers in town who are making preparations to build additional silos for summer feeding, and others say they are going to invest in them; but the chances are that those who are "agoin' to" will not get there, but will be caught again in next summer's drouth, just as they have been each year, almost, during the last two decades. But there will be some, who will profit by this and former years' adversity, by building silos and filling them another year with silage for summer feeding, when the drouth comes.

The creamery promoter shark is playing his little game, or trying to, in this county. As usual, however, he has steered clear of each locality where farmers' institutes are wont to be held, or where HOARD'S DAIRYMAN is taken and read. Just now, if one is to believe the newspaper reports, a Chicago promoter is trying to victimize the farmers of Theresa, this county. Theresa is a town that doesn't take to farmers' institutes very kindly, only one or two, one day's meetings ever having been held there, and these were so slimly attended that no further applications have been put in from there. It is a good place, therefore, for the creamery promoter and aquatic separator can frauds, to work their little games.

At a meeting of the Watertown Produce Exchange, recently, Mr. C. S. Kellog exposed the whole fraud, and told the Theresa farmers to keep out of the deal, giving his reasons therefor. His speech was printed in the Watertown *Standard and Times*, but the chances are that the dupes have never read it, and, notwithstanding all the efforts being made by the exchange, and the timely warnings of the two papers, the promoters will succeed in "roping" enough farmers "into the game," to establish a creamery there or near by, whether there are a hundred cows, or only a dozen in the neighborhood.

Fully eighty factories were represented on the Watertown Board of Trade, Saturday, the nineteenth, and it was reported the falling off in milk receipts at these factories was an average of fully 40%, also that the farmers were then feeding hay, bran, and other mill stuffs to their cows. But these foods will not take the place of green peas and oats, nor well grown corn. Yet, some farmers having corn, refuse to cut and feed it now, when it has nearly reached its greatest value, but are waiting to harvest, cure and feed it in the old way.

Prof. Plumb, not long since, had an article devoted to pure blood stock, in the *Rural New Yorker*, which ought to be printed in every first-class agricultural and dairy paper extant. In it, the folly of rearing and selling every calf dropped, whether of value or not, because it has a pedigree and registered ancestry behind it, was fully set forth. This practice has more fully than anything else, prevented the average farmers from purchasing pure breed sires to bed their herds. So many failures have resulted from the purchase of such sires, that hundreds of dairymen refuse to buy them, preferring to continue the breeding of cross bred or scrub sires, instead.

A few days since I was at Adams, and saw thirty bulls, two to three years old, in the cattle yard, awaiting shipment in the afternoon of that day. They came from Ellisburg, Adams, Henderson, Lorraine and Rodman, all adjoining towns, and had been bought for two and one-half cents per pound. They were of nearly every color or combination of colors, of all shapes and forms, except that of the dairy, and weighed from 700 to 1,200 pounds. Not one of them was worth a dollar for breeding purposes, and had been sold for bologna mill meat, their owners not caring to use them another season. But each of these farmers have another sire, "a son of his father" coming in to take the place of his bologna ancestor next spring, and will in time follow in his foot steps. Ask one of those farmers why they continue the rearing and using of such sires, instead of putting a thoroughbred of some breed into their herds, and they will at once refer you to some one who has invested in such a sire, paying big money for him, and which turned out to be only a scrub, not so good as some of their cross bred or natives. So they at once discarded the thoroughbreds and went back to their old loves.

Had the breeders who sold these full blood scrubs, slaughtered them at sight and sold only those of real merit instead, thousands of farmers would now be using pure bloods. In Delaware County, this state, in the town of Bovina, Mr. Powell and myself did not find a cross-bred native or scrub sire among the 120 herds visited. Every one of them was either a pure bred Jersey or Guernsey. Those farmers had learned the value of such sires, and, while nearly all their cows were either Jersey or Guernsey grades, each one had a thoroughbred sire in his stable. They had learned the modus of selecting a calf that would develop a sire of the desired qualities, and thus seldom made a mistake in their selections. Those calves, whether heifers or bulls, that did not have the requisite qualifications, went to the block. They were neither raised nor sold.

The *Jersey Bulletin*, however, does not favor such a practice, but says, raise everything and do the weeding out later on, when you have learned that the bull or heifer is worthless. One can't tell, it says, from external appearances, what sort of a cow or bull a calf will grow into. Dairy form in a calf don't count; only time will determine its value. Such advice is good for the professional breeder who is looking after customers and high prices based on pedigree and registry, but the average dairyman who wants to improve his herd by grading it up, won't listen to any such clap-trap. He don't propose to pay $25, $50 or $100 for a bull calf that has nothing behind it but pedigree and much talk of its owner; and as developed service sires, that have records, are too high in price to meet the capacity of their pocketbooks, they refuse to purchase, and so continue the practice of using mongrel sires. Among the 365 herds of cows of fifteen each, in this town, there are not more than twenty-five thoroughbred sires. The others are of the types I saw in Adams. Next year, about August 1st, there will be another exodus of these bulls. It is not to be wondered at the small yield of milk—less than 3,500 pounds per cow—in this town. But

Now stocked with Registered Jersey Cattle. For price, terms, etc., address,

MAPLE GROVE FARM, Hocking County. Logan, Ohio.

it will never be increased until mongrel and thoroughbred scrub sires are discarded and only thoroughbreds of merit given their places. That day is somewhere in the future, but not yet in sight.

The *Jersey Bulletin* is now after the scalp of Mr. Rice, of Ontario, who has dared to question the big yields of some of the Jerseys reported in the *Bulletin*. He says the Babcock test has ended the days of such cows and their churn tests. Whereat the *Bulletin* gets mad, calls him "Rice" and says he milks Holsteins, which give thin milk, and asks if he ever heard of chemists who have analyzed the butter from some of these cows and which showed 80% to 85% butter fat, a proof conclusive that Mr. Rice has lied.

No doubt but Mr. Rice has heard of men who sail under the chemist's flag, but who have their price. It was no trick at all, and is not now, for the oleo gang to find chemists to swear to the wholesomeness of their vile compound. Nor do the users of preservatives in butter, cream and milk, or the contemptible wretches who are adulterating every thing we eat, drink or wear, meet with any trouble in finding chemists who will not hesitate to give their wares a "clean bill of health." All that is necessary to secure a certificate is cash enough, and their services can be as readily obtained in aid of the big butter churn tests as of hog butter or adulterated food products.

What troubles the *Bulletin's* soul most, is the failure of the Babcock to find the fat in the Jersey milk, sufficient for such yields of butter, while it finds too much in some Holstein milk. Its only war is waged against the Holsteins. The other dairy breeds, however, i. e., Ayrshire and Guernsey, would catch it just the same if there were enough of them to make a show. The want of respectable—or, rather, competitive—numbers, is all that saves them and their owners, from the abuse of the screed. But they "will catch it" should they ever develop into respectable competitive numbers.

Dr. C. D. Smead, of Logan, N. Y., writes me under recent date, in answer to some inquiries relating to his famous old, grade cow, which, I think, is now past her twenty-second birthday, the following:

"She dropped her last calf on February 10th, last, sired by my Guernsey bull, Rydale. It is a fine heifer calf, having almost perfect Guernsey markings, with the old cow's form, and six well developed teats. The old cow is still hale and hearty; eats six pounds daily of corn, oats and chop mixed, two-thirds being oats. Two months after calving, she produced thirty pounds of milk daily, which tested 4.8 per cent fat. Four months after calving she was giving twenty-eight pounds per day, testing 5.2 per cent fat. At present she is giving twenty-six pounds per day, testing 5.4 per cent. The calf is being raised, and, although I was offered fifteen dollars for it when but six weeks old, I shall keep it and see what it will make.

Her teeth are fairly good now, but I see that it bothers her some to eat hard food, which she will not be compelled to do in the future. She has not been dry since her first calf was dropped, which was when she was about twenty-two months old, but has been milked *every* day since; and there has never a day passed that she did not eat a grain ration of some kind. Her first calf is now running in the same pasture with her, and is the property of my hired man, being his family cow. She also dropped a heifer calf sired by my bull. It is a fine one and is being raised for a cow, and both cows are in calf again to the same sire. I can only hope that both will again drop heifer calves."

We often hear the question, "How long before a cow will wear out, if fed such rations, as you recommend?" asked at the Institutes; and, "Would not the digestion and stomachs of the cow be ruined if we fed all our cows in that way?"

While not all cows will live and produce such yields of rich milk every day during twenty years, nor be capable of eating, assimilating, digesting and paying for such rations, because of a lack of constitutional vigor, there are thousands which would, if given the chance, but which go to the shambles at an early age, never having had "a good square meal" during their life times, except that which they got in the pasture during the few days of June flush. If no more cows died from eating liberal, properly balanced rations, than from a want of them, there would soon be a big discount in bovine funerals in this expanded Republic of ours.

Belleville, N. Y. C. W. JENNINGS.

Cleanliness in Dairying.

A great deal has been written upon this subject, but I think that a few more lines would not be out of place, judging from what I observed today while taking in the milk at the college creamery. It is not at all unusual to find all sorts of filth in the bottom of a can, such as grounds, manure, etc., etc. Such a state of affairs cannot be tolerated much longer if we expect to be able to compete with Denmark and other countries in the leading butter and cheese markets. We must educate the producer in order that he may fully realize the vital importance of perfect cleanliness in dairying. Of the many reasons for the necessity of cleanliness in handling milk, one of the first is that milk is a liquid and will dissolve a large portion of the foreign matter that finds its way into it. When this matter is once dissolved, no amount of straining can remove it. Another reason for giving especial care to the handling of milk would be that from the necessity of the case it is not the so-called unobjectionable kinds of dirt, that are sometimes distinguished as "clean dirt," to which milk is usually exposed, but to the germ-laden dust and obnoxious odors of the cow stable, as well as particles of dried manure, hairs, and other minute particles, so apt to drop into the pail during milking. We must bear in mind that it is not the dirt of itself that gives rise to so much trouble, but that it is the undesirable kinds of bacteria which enter the milk along with the dirt, as they exist in untold numbers in these objectionable contributions. When the forage and bedding are handled just before milking, as is often the case with men who have not made a special study of dairying, a very objectionable kind of bacteria (known as hay bacillus) find their way into the milk with the dust. In addition to the sources referred to, it oftentimes happens that the unwashed hands of the milker, together with some old coat that has previously served a period of more esteemed service, but now serves as a special garment for the grooming of horses and milking the cows, furnishes a smaller, though very objectionable, part to the general supply. Again, we may find that good housewife or domestic who has not learned the superiority of a good brush to the much used dishrag, has been unable to remove all the slimy substance that adheres so tenaciously to the vessels. Thus a supply of bacteria, sufficient for an undesirable seeding, is in this way preserved. Not only is milk liable to contamination from the above named sources, but it is of such composition that when once seeded the bacteria can neither be skimmed off nor strained out, but are there to stay, as it furnishes temperature, moisture and food supply so admirably adapted to their growth and increase, that under these favorable conditions they multiply at an inconceivable rate of rapidity. This increase in undesirable bacteria very materially affects the keeping quality of the milk, thus greatly shortening the time in which it can be put upon the market in an apparently fresh condition. Or if the milk is to be used for the manufacture of butter and cheese, the presence of these germs will prevent a proper ripening of the cream, thus making it impossible for the butter maker to secure that much-sought-for quality, good flavor, in his butter. In the production of cheese they produce gassy and floating curds, which cause the cheese to be spongy and "pinholey." After these things have been considered, there is yet the influence that uncleanliness may exert upon the health of the consumer of the milk or its products, and also as regards securing the best price for the article offered for sale. As regards health, there is no longer any doubt that impure milk is not only undesirable, but positively dangerous, from the disease germs that are likely to abound wherever there is dirt, filth or decay. The milk may not only serve as a means of conveying the germs of such diseases as typhoid fever, tuberculosis, and numerous other virulent diseases, but the decomposition that is set up in the milk by the putrefactive bacteria may produce in milk or its products toxic compounds that are extremely poisonous, and which often produce sickness or even fatal results. This form of poison, as well as various other troubles, develops in cheese also, and is, like other cheese diseases, supposed to be the outcome of improper care of the milk. In butter, one of the most annoying effects of undesirable bacteria is the earlier development of butyric acid and the consequent rancidity of the butter. From some experiments made here at the Iowa College creamery in regard to the keeping qualities of butter made from cream that had been separated from milk which had been exposed to unfavorable conditions that are so frequently to be met with, and other cream that was free from all undesirable kinds of bacteria, I am firmly convinced that uncleanly conditions are more directly responsible for rancidity in butter than is indicated by any authority that I have read upon that subject. I do not hesitate to venture the opinion that if more thorough cleanliness was rigidly practiced by all who put butter upon the market, the reduction in the amount of rancid butter would be sufficient to silence those champions of oleomargarine and other imitation butters who have been successful in persuading so many that these products of the great packing corporations should be allowed to supplant butter as an article of food on account of their better keeping qualities. While it is possible by resorting to pasteurization and pure culture starters, to improve the quality of butter made from milk that has been poorly cared for, I think it is admitted that there is no process by which poor milk can be made to produce the very best butter or cheese. We must also bear in mind that while commission merchants purchase the poor butter with reluctance at a lower price than is profitable to the producer, they are eagerly watching for the very best, and will often pay from half a cent to one cent a pound above market quotations to customers who can always supply them with the very finest article.—W. J KENNEDY, in *Prairie Farmer*.

One of the reasons, that dairying has been profitable to the farmer who undertakes it, is the fact that this industry gives steady employment throughout the year, not only to the farmer himself, but in some measure to his children large and small as well. This factor is of often of the highest importance and brings the dairy industry in strong contrast with grain growing, where labor is employed only a part of the season, to be idle the rest of the time.—*Ex.*

In Washing Paint

don't scrub it and wear off the surface. Use Gold Dust Washing Powder according to directions printed on every package and you will be pleased with the results and surprised at the saving in labor.

Official Tests of Holstein Friesian Cows, from May 1 to June 1, 1899.

These tests are invariably made by Agricultural Colleges and Experiment Stations at the homes of the cows for periods of seven consecutive days. The butter fat is determined by the Babcock test and the butter calculated on the basis of 80% fat to a pound, the rule established at the World's Columbian Exposition.

"Ohio's Famous Herd of Holsteins."

ED. HOARD'S DAIRYMAN:—I had thought you might be interested in a visit paid to the above famous dairy herd, and perhaps its equally famous dairyman, Mr. E. F. Smith, junior member and manager of the firm of W. B. Smith & Son, of Columbus, O.

We have herds of thoroughbred cattle in which interest centers almost entirely in pedigree; other herds in which dairy work is the all in all. Here, I think, we have a happy union of the two ideas. Certain it is that this has been a working herd from the start.

Seventeen years ago this firm took the contract of supplying the state hospital for the insane, what milk it needed and has been supplying it ever since. The herd was composed originally of grade Short-horns; later a few Jerseys were introduced, but not proving as satisfactory as was hoped, they gave place to the grade Holstein, and the latter have been replaced by the thoroughbred Holstein, until it now numbers some sixty cows—perhaps unequaled by any herd of sixty cows to be found in the country. But let me tell you about them.

To get these cows together, Mr. Smith has bought five herds outright and the tops of five more. Any cow proving unsatisfactory has been speedily sent to the butcher. He seldom sells a cow other than to the butcher. One exception to this rule, that has given Mr. Smith no little pain, is the world-famous cow, Calamity Jane, now owned by Geo. Rice, of Canada. This cow was bred and raised by the Smiths; however, the herd has a good many "Calamity Janes" in it.

While some breeders have one or two cows of exceptional merit and trot them out for an official test, "Ohio's Famous Herd" starts them in bunches of a dozen and a half. Ten cows tested last winter by the Ohio Experiment Station averaged 470.65 pounds of milk and 19.87 pounds of butter (80% fat) in seven days.

How does this compare with the World's Fair test, Mr. Editor? When we consider that all these cows are in one herd, and, what is of no little importance, all the tests made by a state official, I think this is a most remarkable record. Remarkable as it certainly is, there are many others of this herd equally good. Mr. Smith will be on deck next winter with another string just as good.

I said Mr. Smith supplied the hospital with milk. It requires about two hundred gallons a day for this purpose. Being located on the hospital grounds and in their barns, he has no room for surplus stock, no feed either for growing calves. His milk brings fourteen cents per gallon, too expensive feed for even high priced calves; accordingly the latter are all sold at seven to ten days of age. From such dams as the above, and from the best sires that money will buy, it is not surprising that the calves are wanted and at good prices. They are usually booked weeks in advance of birth.

Speaking of sires, it must not be forgotten that the herd is headed by Paul DeKol. The Holstein world understands that so far as breeding and transmission is concerned, he is without a peer.

The herd averages as a whole eleven and one-half thousand pounds of milk per head, per year and tests on the average 3.6%.

The cows are milked about ten and one-half months and freshen every month except April and May. They are for the most part dehorned.

Back of every famous dairy is a famous dairyman. And in this case back of the dairyman is HOARD'S DAIRYMAN. Money will buy a good cow, but it will not feed or breed one. Cow sense is as essential in dairy management as horse sense is in the world in general. Mr. Smith is richly endowed with this commodity. Handicapped in his feeding, in that a foolish prejudice of the hospital authorities will not allow him the use of ensilage, yet he (I don't know what better to say) "get's there just the same."

Dairymen passing through Columbus, O., can spend an hour very profitably at the hospital barns. Mr. Smith is chock full of "cow" and unwinds at slight provocation. His house is full of silver cups and plates won at dairy tests and state fairs.

I have asked him for a photograph or two which readers of the DAIRYMAN will doubtless like to study. C. G. WILLIAMS.

Concerning the Raising and Care of Calves on the Farm, and Matters Connected Therewith.

ED. HOARD'S DAIRYMAN:—There is a considerable advantage in raising calves on the farm, where a part of the cows come fresh in milk from September to December, and the remainder in spring. This method results in having milk the year round, thus enabling the farmer to raise a certain number of calves in the fall, or what can be conveniently cared for, and what more is wanted in the spring.

If a farmer has good comfortable quarters, where calves can be kept during the winter, those dropped in autumn will get well started before cold weather, and with proper management, grow thrifty right along, regardless of the season, and by the time that grass grows another spring, be in prime condition to go to pasture and get their own living.

In this way there will be milk for both calves and pigs during the winter, and then, as more come along in spring, another lot should be started, that should be fed well along into the summer. This method divides the work of calf raising, and makes it possible to rear more, if it is desirable, than if all were to be raised in cold or warm weather.

We have some very fine heifer calves, that came along from the last of September until December, and having good care during the winter, were turned to pasture in the spring, when they refused their milk, weaning themselves and without the usual noisy complaint.

With warm, comfortable pens, and good care, I like very much the raising of winter calves.

These animals will come to the barn another winter in a condition to grow right

along, and will be a long ways ahead of those raised in the spring.

I notice there is a good deal of difference in the size and appearance of the calves—mostly spring raised—one sees in passing along the road. Some are good, others middling, and the remainder, far too many, small and inferior.

This illustrates pretty well the care and attention that is bestowed on this branch of farming, and the character of the owner, or the one who does the work.

A sorry sight is a lot of small, poor, ill cared for calves, as it comes along toward winter. If the same care is extended through the cold weather, what will these animals be by another spring? If they do not die, they will not be worth as much as a good calf should be at the commencement of the winter.

Our dairy stock should have good care at all times, and especially is this important with the calf up to the time that she becomes a cow. A well fed and cared for heifer is now as advanced and good for the dairy as used to be the case years ago at three years old. And this same management often doubles the value of our cows, as milk and butter producers.

Every farmer and dairyman will certainly consult his own interest in faithfully caring for his animals. Endeavor to have them come to the barn at the commencement of winter in good condition. Then keep the younger ones growing right along, and the cows yielding a fair profit on the care and feed bestowed.

If there is to be milk through the winter, raise some promising heifer calves to take the place of the older cows in the dairy; make the conditions for this purpose the best possible, and see if the results do not justify all the labor and expense incurred.

Franklin Co., Vt. E. R. TOWLE.

Use and Value of Lupines.

Among nitrogen-producing plants suitable for green manuring, the lupines have long held a prominent place. There are three species of cultivated lupines, called blue, yellow and white, after the color of the flower. All are annuals. The lupines thrive upon the most sandy and barren soils, where not even rye will grow. They have very long roots which penetrate light soil to the depth of six or eight feet. These plants are all quite hardy and when properly treated, yield a large amount of vegetable matter, which is very rich in nitrogen. The growth, however, is entirely worthless for forage, as it contains a bitter, poisonous substance, called *lupulin*. The lupines yield a great amount of large seed. In Europe the seeds are crushed and macerated in water for a day or two. This washes out the injurious substance, and the residue makes a good food for sheep.

In the United States land is still so plentiful and cheap that lupine soils are not considered worth cultivating, except in some localities where early vegetables and stone fruits are grown for market. On better soils crimson clover will yield more profit than lupines. Lupines may be sown in spring in the northern, and in fall in the southern states. The seed is usually sown broadcast at the rate of forty to sixty pounds per acre, and covered in to the depth of three to four inches. The plants, when suitably fertilized are vigorous growers, and one plant spreads out till it occupies a square yard or more.

The seed of cultivated lupines is nearly all imported and costs about ten cents per pound. Like all leguminous plants the lupines draw upon the free nitrogen of the air for the more costly part of their food, and fix this in their tissues, which when turned under, become available for non-nitrogen gathering plants. Chemical analyses show that one ton of green lupines contains of nitrogen eight and eight-tenths pounds; phosphoric acid six pounds; potash seventeen and three-tenths pounds. The average growth on well fertilized soil is six tons per acre, which at the prices of commercial fertitizer makes the fertilizing value per acre worth about $20. Of this $20, $8.00 represents the value of the nitrogen taken from the atmosphere, $1.80 is the value of the contained phosphoric acid, and $10.38 that of the potash. Both the latter substances must come from the soil. As the very sandy soils, on which lupines are ordinarily grown, contain naturally scarcely a trace of either phosphoric acid or potash, both these substances must be supplied in the fertilizer, or it will not pay to grow lupines.

A good fertilizer for lupines is acid phosphate 600 to 800 pounds per acre, kainit 800 to 1,200 pounds, or muriate of potash 200 to 300 pounds. Lime and marl are also needed where a permanent improvement of the soil is needed.—GERALD MCCARTHY, in *Country Gentleman*.

THE USE OF MILK PRESERVATIVES.

The Special Harm of Formaldehyde—It Checks Digestion.

In a recent article on pure food legislation, the *American Druggist* alludes to the means sometimes employed to preserve milk in hot weather. In New York State the employment of boracic acid, salicylic acid and sodium benzoate are prohibited strictly. So, too, is that of formaldehyde. Of this latter drug, the periodical referred to, says:

"Its peculiar advantage for this purpose lies in the fact that only a minute proportion is necessary for preservation, and that it was supposed to exercise no restrictive action on the digestive processes. During the last few months, however, this latter supposition has been widely challenged, but it is only recently that satisfactory experiments have been carried out, leading to the conclusion that formaldehyde, even in minute quantities, exercises a decidedly inhibitory action on the process of digestion.

"A series of experiments carried out by Dr. Frank Morrison, President of the Indianapolis Board of Health, for the purpose of definitely ascertaining this fact, showed that in a dilution of only one drop to a gallon of milk, formaldehyde delayed its digestion in artificial gastric juice for several hours, while the addition of ten drops almost entirely stopped the digestive process. Dr. Morrison's experiments show conclusively, that even the smallest trace of formaldehyde delays the processes of digestion. It may be objected that test tube experiments are no criterion of what goes on in the human stomach, and while this is, to a certain extent true, the natural process of digesting milk is so nearly approached in the test tube that, provided comparative experiments are made, the results may be accepted as fairly accurate.

"Dr. Morrison has also made a large number of experiments on animals, and, we understand, that the results from these experiments confirm the results obtained by artificial digestion. While there may be some difference of opinion as to the advisability of using preservatives in certain articles of food, all important authorities agree that milk is not a proper subject for the addition of any chemical preservative. It seems to be a food which is only suitable for use in the fresh condition. Decomposition should be prevented, either by the use of ice or by pasteurization, and not by the addition of any foreign substance. Even the latter process is open to objection, on account of the changes which it causes in the natural proteids of the milk."

CONCERNING OUR ADVERTISERS.

BY the advertisement of L. V. Axtell, Perry, O., it will be noted that the Old Homestead herd of Guernseys will, this fall, have representatives at Ohio, Wisconsin, Indiana and Illinois State Fairs. We trust readers of the DAIRYMAN will not loose the opportunity of a better acquaintance with this herd.

WRITE for the catalogue of Fairbanks, Morse & Co., Chicago, Ill. Their gasoline engine is a winner and their whole line of goods are known for quality. They are advertising with us and would be glad to send catalogues if you will mention HOARD'S DAIRYMAN.

"Your Boyhood Days" is the seductive head line of the very neat and attractive advertisement of the Hartman Manufacturing Co., of Elwood City, Pa., which appears elsewhere in this issue. The cow and the cat and boy and their attitudes will certainly bear out the declaration of the first line of this ad. By the way, this picture is a reproduction of a photograph taken from life. The Hartman people have had a large number of copies stricken from the original plate and printed on extra heavy paper. The whole makes a very pleasing little picture suitable for framing and will be mailed to any address on receipt of a two cent stamp.

While the Hartman Steel Rod Lawn Fence is subjugated in the picture we might say just here that it is a very neat and durable fence which materially adds to rather than detracts from the lawn.

IN the last issue can be found the advertisement of the Janney Mfg. Co., of Ottumwa, Iowa., placing before the readers of HOARD'S DAIRYMAN their combined corn husker and fodder shredder. There is no combined machine for this work on the market that receives so general an endorsement from its users. There are hundreds of the readers of the DAIRYMAN that might find this machine a great saving to them and as this company are more than pleased to forward circulars and complete information as to construction and capacity, we trust they will, at least, chance a postal card to obtain it. The following from one of the users of the machine, is certainly an excellent endorsement:

"JANNEY MANUFACTURINGCO., Ottumwa, Iowa.—GENTLEMEN:—The eight roll Corn Husker we purchased of you in October, 1896, has given us entire satisfaction in every way. It husks the corn clean and shreds the fodder in the best possible manner for feeding stock. We have a dairy of fifty cows (50) cows, and we value the corn fodder, when shredded, equal to timothy hay, for feeding cattle.

We have husked about twenty thousand (20,000) bushels on an average each year, for ourselves and neighbors. We use a traction engine to run the husker. Corn can be husked in the fall just as early as your corn will do to crib, and the fodder, when shredded, can be stacked in the field or put in the barn and keep good. We have tried it for the last three years, and find it keeps good, but corn must not be husked when it is wet with rain, any more than you would stack hay with water in it, but no trouble about fodder keeping if stacked in the field.

Our machine husked as fast and as clean the last year as it did the first year. The husking pin you have in the rolls, is made to husk corn and it will do it too, and being reversible makes it the best husking pin made. We husked forty thousand (40,000) bushels and then reversed our husking pins, and we again had a husker that would husk as good as when new from the factory, and that we consider a great advantage in your husker.

Yours truly, SMITH BROS."

Ringwood, Ill.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

FAILURE TO BREED.

Have a fine Guernsey heifer, seventeen months old, which so far fails to get with calf. Has been served at each time she comes in heat, which is every twenty to twenty-one days; was first served at eleven months old.

Mickleton, N. J. W. H. B.

ANSWER.

Yes, there can be something done for your heifer. First, stop bulling until she has been prepared for service, Bulling, as I have kept on stating for ten years in the DAIRYMAN, is the most ruinous of anything in all such cases. The advertised remedies may be tried.

FOOT AIL.

A number of cows in our district, including five of our own, have been affected with a severe lameness in one of their fore feet; lasts for about a week, then they seem to recover. Don't think it a case of broken hoof; trouble seems between the hoofs.

Stonenall. J. M. D.

ANSWER.

Foot foul, foot canker, foot ail, etc., etc., such have you and your neighbors, and I think all from the same source. Some form of filth may be in the roads, in the pasture, in the barn yards, etc., etc. First see to, find out and remove the cause. Wash between the clefts of the hoof, thoroughly, with hottish water and tar soap. When quite dry, soak a piece of cotton batting or sponge in Tilden's Bromo Chloralum, one to eight of cold water Let this be done three times the first day. Next day change to Pyroligneous acid twelve ounces, fish oil thirty ounces; soak another piece of sponge in this and crowd to the very bottom of the cleft. Do this daily until not needed. Remove the cause.

LUMP ON KNEE.

I would like to ask about one of my cows. She has a lump on her knee about the size of a man's two fists; looks something like a wind puff only hard. On the same shoulder there are a number of small lumps, each about as large as the top of a man's thumb. She seems to be in perfect health, only she gives very little milk.

A SUBSCRIBER.

ANSWER.

Your cow is of a scrofulous diathesis. I would not attempt to doctor her. I would not, under any circumstances, use the milk; it is impure. Cows, nor anything else are fit to propogate from with such constitutional defects, as nature is ever persistent in bequeathing such defects to her descendants. This law is established beyond contradiction.

Horse Owners! Use GOMBAULT'S Caustic Balsam

A Safe Speedy and Positive Cure

Summer Feeding.—Fly Repellent.

ED. HOARD'S DAIRYMAN—I noticed W. K. M's inquiry as to whether I have "adopted soiling for cows in summer." I did that six years ago, and one year was enough. I built a summer silo and found the trouble so small as compared to cutting and feeding the green food that I planted a few acres more corn for summer and put in the silo.

We had to fall back on soiling this summer, as a frost struck our corn field on July 10th, 1898, causing a loss of twenty-five tons, and now, notwithstanding green peas and oats and green corn, our shrinkage, as compared with feeding silage in the summer, last year, is at least 20%. At the end of my new barn I have built two silos, 14×30 feet, holding nearly 100 tons each, and have corn enough growing to fill them. We feed six pounds of bran the year around and in the fall and winter, three pounds ground oats, additional.

Having a new and commodious stable, with thorough system of ventilation (not quite completed), I propose another year to keep all milk cows in the stable in the daytime in summer, darkening the stables. I have watched closely the effect of the flies on the production of milk this summer. We use seal oil one gallon, crude carbolic acid, four tablespoon-fulls, and put on with a horse brush.

This lasts about a week, when it has to be renewed. We do this each Monday morning, and on looking at the milk sheet for the Sunday evening and Monday morning and compare with the Monday evening and Tuesday morning there is frequently a difference of from five to ten per cent, in the whole herd, some cows more than others.

If the cows are kept in a dark stable, with good silage and meal, they would not be wasting their food (energy) fighting flies and traveling up and down bare pastures, consuming all they get in endeavoring to keep their bodies alive, as I have seen this summer. Is it any wonder the dairy cow does not pay in the hands of the shiftless keeper of cows?

Uxbridge, Ont. J. E. G.

Improvement of Herds.

There is no subject more interesting to agriculturists than the improvement of the animals on the farm; the study of them in consequence holds the highest rank. We think a report upon this question should be developed in a very precise method.

We would consider, first, the improvement of the herd in general, its interests and its profits.

Second, the way to succeed in the improvement of the herd.

The first question to which the attention of the farmer is directed should be the constitution of his herd, and we do not hesitate to say that an incredible number of cultivators occupy themselves very little with this question. They consider the animals necessary things. They forget that an animal with many qualities gives to its product the best, and that it costs no more to nourish a good animal than a bad one. We see every day in the villages the farmer conduct the cow to the bull at his neighbor's, because his stable is convenient or the price of breeding is cheap, although the reproduction be of mixed race and deplorable form, while a little further on is found a bull of pure blood and better conformation.

In almost all the country the same apathy appears, and certainly our efforts should be especially directed to persuading those interested that the improvement of the animal is one of the first conditions of a good culture. The form of the animals should be the first consideration, not only because it should be beautiful to the eyes, but because the animal with the best conformation gives the best profit. We should seek to produce the most flesh and the least bone to render the merchandise useful.

An animal badly constructed gives defective prices, and experience demonstrates to the contrary—that when his lines are regular it is always more profitable for the seller and the butcher, when he terminates his career and accounts are settled.

It must be admitted, then, that the animal well constructed is advantageous to the breeder, and that greater care in breeding gives increased profits.

In many cases the milk is the most profitable feature of the farm. The making of butter and cheese, the utilization of the milk and cream for the workers on the farm, and also, for the nourishment of calves and hogs—for none of these should be neglected. We conclude this first point with the following résumé: The utility of the improvement of the animal, in its form, in its construction, in its qualities, in meat and in milk, cannot be doubted. This is evident to those who are at the head of progressive farming, but a long experience has convinced me, with certainty, that it is exceeoingly difficult for these new ideas to gain admittance among the agricultural classes, and that it is only by unceasing efforts that any good effect can be produced.

This should all be thoroughly discussed, and in order to penetrate under the thatched roof of the small contractor, the first attempts at improvement should be of the most elementary character.

Second, the way to succeed in the improvement of the herd. This is the question: How shall we improve the herd? The first thought that presents itself to us is selection. It is evident that in countries where the races are of good quality, the most natural way of improvement is to always eliminate the bad animals and preserve for reproduction only the choicest. This is the first procedure and in every case is always imposed, but it is often inefficient in the sense that it rarely succeeds in correcting the principal faults that are developed in a race by long breeding, and must disappear slowly.

In order to produce a real and true effect, efforts must be applied with great spirit, not only among individuals the more cautious and intelligent, eliminating without mercy the bad and mediocre animals, but it is necessary that the whole mass of breeders join their forces in improving their herds, and continue during several generations.

It is very rare one finds a community with the courage to give up the old habits and accept and apply without hesitation the new procedure. The selection is therefore extremely important, and should be made with the greatest care and attention by those who understand well its importance.

It is not by judicious crossing that one can operate happily and readily. The crossing of two distinct races should never be made at hazard, but should be a serious study and with profound examination.

We often hear these expressions: "My herd has such faults! I will take a bull of some other race having the qualities desired." This is the gravest of errors. All the attempts imaginable that have been made have only affirmed, in the most peremptory manner, that races cannot be mixed without greatest prudence, or the results may be most deplorable.

We repeat, then, that the most effective way of improving stock is by careful selection.—*Journal d'Agricultue Pratique.*

THE JONES UMBRELLA "ROOF."

A NEW UNION TWILLED SILK "ROOF" $1.00

RE-COVER YOUR OWN UMBRELLA.

The Adjustable "Roof" fits any frame, requires no sewing, and can be put on in a minute. You can re-cover your own umbrella without the slightest trouble or moments delay.

Take the measure (to the fraction of an inch) of your old umbrella; count the number of outside ribs; state if the center rod is steel or wood; send to us with $1.00 and we will mail postpaid, a Union Twilled Silk 25 or 26 inch Adjustable "Roof" (27 or 28 inch, $1.25; 29 or 30 inch, $1.50). Umbrella "Roofs" all sizes and prices from 50 cents to $8.00 each, according to quality. If you are not absolutely satisfied in every particular, send the "roof" back, and we will refund the money *at once*, including stamps you have used for postage. Over a quarter of a million "Roofs" sold.

Booklet, "Umbrella Economy" with simple instructions necessary with your order.

All first-class dealers sell Jones Umbrella "Roofs."

The Jones-Mullen Co., 396-398 Broadway, New York.

Manufacturers of the highest grades of Umbrellas to the largest stores in the world.

When you dream that somebody is pushing you over a precipice it's time

you looked after your stomach and liver. You may not believe in dreams but that particular sort of dream is likely to come pretty near true if you don't take prompt measures to prevent it. If you neglect the warning you may find that you are actually pushing yourself over the precipice of disease into the abyss of death.

Don't forget that your heart and lungs and brain and nerves are supplied with blood and nutriment through your stomach, liver and bowels. If they do not do their work properly — if the blood is full of poisonous matter your whole body will soon be full of impurity and disease, and it is small wonder you dream of disaster.

Dr. Pierce's Golden Medical Discovery purifies and enriches the blood. It cleanses the whole digestive system and is an antidote for poison in the blood. It is a blood-maker and flesh-builder and is good for the nerves. It brings restful sleep and a clear head. It contains no alcohol, whisky, sugar, syrup, or dangerous opiates.

"I used Dr. Pierce's Golden Medical Discovery and 'Pleasant Pellets' and have had no trouble with indigestion since," writes Mr. W. T. Thompson, of Townsend, Broadwater Co., Montana. "Words fail to tell how thankful I am for the relief, as I had suffered so much and it seemed that the doctors could do me no good. I got down in weight to 125 pounds, and was not able to work. Now I weigh nearly 160 and can do a day's work on the farm."

THE NEW BOOK Feeds and Feeding

By Prof. W. A. HENRY,
Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:

"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

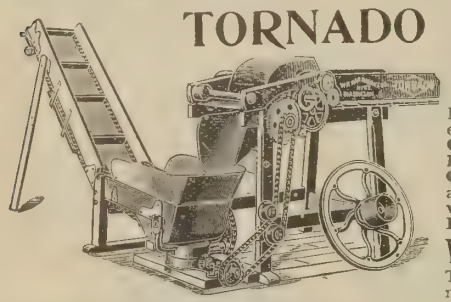
SMALLEY MFG. COMPANY, Sole Makers, MANITOWOC, WIS.

MAKE ONLY SWEET ENSILAGE

Ever since the ensilage system has been introduced in this country it has been the ambition and effort of siloists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste.



The best way to Shred Ensilage is with the

St. Albans Ensilage and Fodder Shredder.

It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail free a pamphlet on the subject.

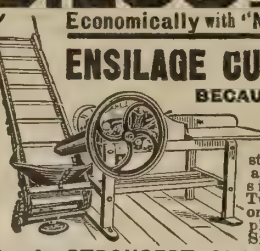
Attention Dairymen!

THE LARGEST PREMIUMS ever offered for Dairy Products in the state is now provided in the dairy department of the **WISCONSIN STATE FAIR,** to be held at **Milwaukee, Sept. 11, 12, 13, 14 and 15, 1899.** Every creamery, dairy, or cheese factory in the state should make an exhibit. Remember if you do not win the Sweepstakes Prize you are sure of your share of the pro rata premiums, which for butter amounts to over $360, and for cheese $330, besides Special, and that duplicate score cards with all special defects, if any, written thereon, will be mailed to each exhibitor in a sealed envelope. Now is the time to make the dairy department of the State Fair what it should be—second to none. Wisconsin Dairy School Students are especially invited to exhibit samples of their dairy products. All exhibits will be carefully looked after and taken direct from the Express Wagon to the large glass Refrigerator in which it will be exhibited. Special attention will be given to re-shipment or selling exhibits at close of fair according to directions received; this will be under the personal supervision of Prof. E. H. Farrington, of the Dairy School. All articles, after being receipted for, will be taken direct from the refrigerator by the Express Co. Exhibitors should write their name and P. O. address plainly on bottom of each package.



All manufacturers or dealers in dairy supplies are specially invited to exhibit. At the Fair is where you will find the wide-awake, progressive and enterprising dairymen, and these are the men you want to show your goods to.

Address all communications in regard to Entries to **JOHN M. TRUE, Sec'y, Madison, Wis.**

P. S.—We are the only Plow Factory in the United States selling implements direct to the consumer.

Convince Yourself.

Does it ever occur to you that a practical demonstration of merit is worth more than the "tale of woe" which comes from a salesman with "an ax to grind?" It is remarkable how wonderfully interested in the welfare of the creameryman (?) some wild eyed competitors of the Tubular have become. Why are they so energetic in their efforts to prevent creamerymen from giving the Tubular a trial? Because they are trembling in their boots. Do they fear that the creameryman will be the loser? Oh, no! Because it is the last card they have to play, and they know that when the Tubular is given a fair trial it gives satisfaction and proves itself in every way superior to their back number machines. Some of these fellows have been weeping "crocodile tears" over Mr. J. A. Chillqvist, of Nettle Creek, Illinois, but the foll wing letter from this gentleman shows that it has paid him to use his own judgment rather than listen to false friends:

NETTLE CREEK, ILLINOIS, August 4, 1899.

The Sharples Co., Chicago, Ill.

Gentlemen: Your letter of inquiry of a recent date was duly received and should have been answered sooner but from the fact that I wished to see fully what the Tubular would do. I have now fully decided after carefully testing the machine, and am prepared to say that it meets fully your recommendation and even more, as it requires very little power to operate same, and the cream is equal, and I believe superior to any separator that I have ever used. I have used separators for the last fifteen years, including nearly all makes. Danish-Weston was the first, then De Laval and Sharples, also Alpha, all of which I considered good, but now I say from experience that I regard the Tubular Separator as the leading machine. I was warned against using or buying this, as it was an experiment; it has proved to me the right kind of an experiment. What can we expect unless we look to advancement. I am skimming 2500 pounds per hour and this not to exceed .03 to .05 and have always found that my own judgment has served me better than the talk of competitors, agents of separators or anything else. There are several Tubulars running near me and all are more than pleased with results from their machines. Yours truly,

C. A. CHILLQVIST.

The Sharples Tubular Separator.

Represents the latest great advance in cream separator construction. More revolutions, less speed, more centrifugal force, less power, more perfect cream, less fat in skim milk, more durability and less complication.

The Bowl alone Revolves. It is a Hollow Bowl. It Spins on Air. Placed on Trial and Results Guaranteed.

THE **RUSSIAN BABCOCK TESTER**

is in use in the best and largest creameries in the United States.

It does rapid work and does it accurately. It is built for the man who has become tired of the old rattletrap tin tester that must be renewed every year or two. It is made of cast iron, **fitted with ball bearings and accurate glassware.** Send for illustrated Catalogue, No. 51.

We are prepared to repair all cream separators and have the most experienced men for this kind of work.

ELGIN MANUFACTURING CO., ELGIN, ILL.

The Perfection . .

Chemical Fire Extinguisher

Thousands OF DOLLARS' worth of property and many lives are lost every year from Fires which could have been easily extinguished with one of these machines.

It is a handsome, highly polished solid copper machine, affording perfect protection from fire. Indorsed by all the leading insurance companies.

It should be in every creamery, cheesefactory and home.

Equal in every respect to the high priced extinguishers. No valves to get out of order. Always ready to use. Turn bottom end up, and it will throw a stream of fire destroying chemical fluid 50 feet. Each machine tested to 200 pounds per square inch, and fully guaranteed.

Price within the reach of everyone. Let us quote you.

The National Export Exposition.

At Philadelphia, Pa.

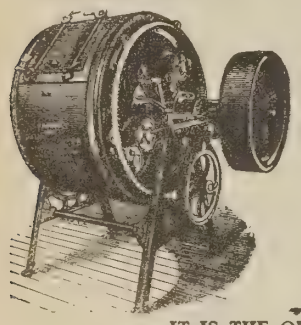
For the advancement of American Mannfacture and the extension of Export Trade; opens September 14th and closes November 30th, 1899.

This will be the most elaborate and extensive exposition of its kind ever held in our country. The exporting of Dairy Products is one of the largest items of American Commerce, and we intend to be "Right in Line."

We will exhibit a Model Milk Distributing Plant, exhibiting in actual operation our Mechanical Refrigerating Plant, Potts Pasteurizer, De Laval Separator, Bottle Filler, Ideal Steam Turbine, and new Acme Belt Bottle Washer, Sterilizing Oven, Disbrow Churn, etc., etc. In fact, exhibit the most complete collection of Modern, Up-to-date Apparatus for handling Pasteurized Milk for retail trade.

It would pay you to take advantage of the cheap Railroad Excursions, and visit this exhibit and become acquainted with the modern process of handling milk.

We should be glad to have you write us at Philadelphia, care of the National Export Exposition. We will have representatives there to give you any information in regard to any apparatus necessary for such a plant.



Alpha De Laval Separators, Ideal Turbine Testers, Disbrow Churns, Elgin Style White Ash Tubs, Ideal Corrosive Sublimate Tablets, Parchment Paper, Australian Boxes, Refrigerating Machinery, Boilers and Engines, American and Lusted Printers, Genesee Salt, Potts Pasteurizer, Etc., Etc.

Dairymen, when Visiting the State Fairs,

BE SURE AND LOOK UP OUR EXHIBIT.

There you will find our representatives who will be pleased to show you

The Improved U. S. Separator

and explain its many points of excellence. Be sure and investigate its merits before purchasing any other make. It is fast being recognized as the best for every day use.

The U. S. the Queen of Separators.

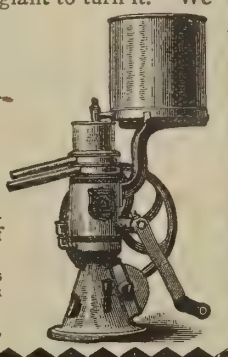
MIDDLEBURGH, N. Y., August 10, 1899.

About a year ago I desired to purchase a separator, and naturally I examined very thoroughly the different ones advertised. Becoming convinced that the Improved U. S. was the best, I accordingly purchased one, and a full trial for over a year has proven the wisdom of my choice. It is the most perfect in construction, skims perfectly clean, runs so easily that a child can operate it, and, in fact, is the acme of perfection. It is the queen of separators, and it affords me great pleasure to forward this unsolicited testimonial.

J. E. YOUNG.

Should you be unable to attend your Fair or fail to find our exhibit, drop us a postal to that effect and we will send you our latest illustrated pamphlets.

VERMONT FARM MACHINE CO., Bellows Falls, Vt.



A Hand Separator

to be profitable must not only extract every particle of butter-fat from the milk, but must run so easily that it does not require the strength of a giant to turn it. We guarantee the

Empire Cream Separators

to run 50 per cent. easier than others of equal capacity. Their record for clean skimming is unequalled. We have the most complete line of hand separators in America; also power machines.

We have not space here to tell you why the **Empire** machines excel all others, but it's all in our catalogue. Send your address if you have one cow or one thousand.

U. S. BUTTER EXTRACTOR CO., Newark, N. J.

H. E. Cook, the noted dairyman of Lewis Co, N. Y., says that in a dairy of 100 cows, in twelve years, he has raised the product per cow, from 3,000 pounds to 6,000 and 7,000 pounds, simply by changing from "dual-purpose" breeding to "specific-purpose." And yet there are thousands of dairy farmers who prefer the beefy, 3,000 pound cow to one which will yield 6,000 pounds. In reality, they have never looked into the question beyond being governed by a loose sort of notion. It is a queer basis for men to do business on, but it exists neverthless.

At the Kansas Experiment Station, the question was put to the patrons of the Meriden creamery: "What farm or dairy paper do you take?" Out of seventy-seven patrons, who answered this question, fifty-three took no farm or dairy paper.

In looking up the details of the records of the patrons it was interesting to note that the highest yield was made by a man who takes both dairy and farm papers. The man with a "farm paper" was getting from $60 to $80 worth of dairy products from one cow, while the man who had no time to read was getting $20 to $30. Secretary Coburn, of Kansas, very well said: "Muscle, to win, must be lubricated with brains."

"PERFECTLY SATISFACTORY."

The illustration on this page was made from a photograph sent us by Baldwin Bros., of Adrian, Michigan, and represents in their own words, "one of our herd of special-purpose cows. The position is rather bad, but it shows what she is, and her performance at the pail is perfectly satisfactory."

We are not told what breed, or breeds, she represents, and if one should attempt to judge from the picture, the chances are, a mistake would be made. It would seem possible, therefore, for all of us to study this illustration without bias of any kind, and learn something about the general appearance and special points of a cow whose performance at the pail, which is the ultimate criterion of merit, is perfectly satisfactory to her owners.

It is true the position is constrained, but this may be rather a help than a hindrance to right conclusions. It helps us very much in coming to a judgment upon cattle, whether from personal inspection or from a picture, to get away, in the first place, from the first impressions which come from looking at the animal as a unit. The beauty of outline and the stateliness of pose which have been impressed upon us by the artists who draw from life (?) are not without their influence, and the handsome cow has an undue advantage, when only dairy merit is to be considered.

Try covering all but the rear third of this cow, and then make a critical study of the form and anatomy of the exposed third, with a view to forming some definite conclusions as to the relation of the several parts to the work required of them, and the ulterior purposes they must serve. For a cow to be perfectly satisfactory at the pail, there must be not only an udder but a place for it and support for it, and these must be so formed and disposed, as to enable the udder to perform its function with the least friction and wear and discomfort to the cow.

Having finished a study of the rear third, cover that, and uncover the middle third, and give it the same kind of an examination and study. Consider what the internal organs must accomplish in order to supply the udder with the material required to enable her to perform satisfactorily at the pail. The cow cannot make milk from nothing; cannot deliver from her udder more than goes into it

Follow the same system with the front third, and when each has been examined and passed upon, defects and excellencies balanced, look at the animal or the picture as a whole, and note whether the several parts (thirds) correspond with, and mutually assist and reinforce each other.

Having done this, we feel confident that reasons to corroborate the conclusions of the owners, will be apparent; and when the same processes of examination are applied to other cows, a very close approximation can be made to a correct judgment in regard to their dairy ability. It is immaterial to what breed the cow may belong. Unless she has the true dairy conformation, in addition to the specific breed requirements and peculiarities, she is likely not to prove satisfactory at the pail.

The breeder should not neglect the breed points, but for the working dairy, these are of subordinate importance.

A COW WHOSE PERFORMANCE AT THE PAIL IS PERFECTLY SATISFACTORY.

Property of Baldwin Bros., Adrian, Michigan.

Valuable Abortion Experience.

Much loss and disappointment is being experienced in many dairy sections, both east and west, in consequence of abortion. One of the most valuable communications to this paper on this subject was by F. E. E. of the North Carolina Experiment Station, in February, 1896. We reprint the essential portion of the same to show the value of thorough disinfection in the treatment of this disease:

"In regard to abortion I wish to make a few remarks. Abortion has seldom came under my notice until within three years. I have read and heard much about the ways in which it comes and goes, and have seen a case or two. It seemed to have dropped down on this farm, and we had to grapple with it. We do not believe in charms, or "wearing itself out," or "medicine" which you give by the mouth, and some statements we have seen of cows "threatened to abort," etc., we pass over. Our diagnosis was abortion, though we had not some of the symptoms dwelt upon by Prof. Nocard in his report to the French government.

In April, 1894, Nocard's treatment was begun. The stable and shed were thoroughly cleaned, and treated with copper sulphate solution, one and one-half ounces to a quart of water, sprayed around freely. Two or three inches of shed bottom was removed and carted away, and plowed into a field where animals do not run, and fresh earth was put in its place. Then during that summer, once in about ten days, the spraying was repeated. When this was done the first time, the cows were tied in stalls and wiped over with the following solution, recommended by Prof. Nocard, who had then had no opportunity of testing its effects or efficiency: Distilled water (rain water in our case) four and one-half gallons, glycerine and alcohol (36°), each, three and one-fourth ounces, and bichloride of mercury, two and one-half drachms. The cows received an injection of this per vagina two or three weeks in succession, but it seemed two strong and that was dropped from our treatment. This accords with a later recommendation from Prof. Nocard, which we saw a little later for the first time.

When the first cleaning up was done, the cows were sponged around tail, vulva, and adjacent parts, special attention being given to the tails, so if any "germs" were there they would be destroyed. This sponging became a part a of the daily work, and it was proposed to keep it up until a cure was effected.

Cows were held back in breeding for fall and winter of 1895, and have now all come in with healthy calves, save two, one of which was suspected to have been injured, and the other may be, or not, a case of abortion.

Of the last calves, one was born dead or at least was dead when first seen, with no appearance of having moved itself. Of all the calves we now have from cows which have previously aborted or have been in contact with them, two were premature, but are active, vigorous calves. We believe the disease is headed off. Also that it can be stopped on any other farm by this means and care not to, by any practice, spread the disease. Your correspondent has this case now to encourage him to undertake the eradication of the disease. If he has faith in germicides, and will use them persistently, there is hope for him. F. E. E.

N. C. Expt. Station, Raleigh, N. C.

Misleading Retailers.

Chicago Oleomargarine Makers Resort to Misrepresentation.

In their desperation, the oleomargarine dealers have resorted to some of the most ridiculously flimsy "guarantees" to their cats-paws, the retailers, which business men have ever been guilty of perpetrating.

In an effort to encourage retailers to continue to palm oleomargarine off as butter, they have guaranteed to protect them against prosecutions, but always take pains to state that their guarantee is against results under the law which "has been declared unconstitutional."

Two weeks ago *Chicago Dairy Produce* printed the guarantee of one William J. Moxley, in which he attempted to mislead his customers to believe proceedings were being brought under the anti-color law passed in 1897, and in regard to which there was a disagreement among Cook county judges regarding its constitutionality. Now comes Braun & Fitts, the second largest makers of the outlawed article, with a decoy in the shape of a guarantee, which reads as follows:

"Every licensed butterine dealer in Chicago has received circular letters from the secretary and attorney for the 'Illinois Dairy Union,' promising all sorts of trouble to dealers in butterine, (that honest and pure article of food.) Well, now, don't you believe a word of it; there is a law against blackmailing and we want now and here to go on record to the assertion, as an affidavit, that we shall civilly and criminally prosecute any man or party of men interfering unlawfully with the butterine business in this or any other state.

"We know just exactly where we stand; we are properly advised on the subject; and now we make you a 'fair offer'—'handle our goods as you always have, we in turn promise and guarantee full protection against the state law (which has been declared unconstitutional) to the extent of paying cost of prosecutions, fines, and stand all costs pertaining thereto.'

"In declaring the law unconstitutional one of the judges stated to the effect 'that the "butter ring" were in his opinion liable to prosecution to recover damages done an honest industry.'

"Fair enough, isn't it? Renew your efforts, and be assured that we will be prepared to fight any number of rounds in any kind of a legal fight, to the finish."

The reader will notice two things. First, this company states that "we shall civilly and criminally prosecute any man or party of men interfering 'UNLAWFULLY' with the butterine business in this or any other state." This is about the plainest piece of "bluff" ever sent out to brace up the failing courage of a class of men who are being arrested daily, in Chicago, for practicing a fraud upon the public. Anyone who "unlawfully" interferes with anyone's business may expect to be proceeded against, either civilly or criminally. But the prosecutions in the city of Chicago are being brought lawfully, under laws which were passed nearly twenty years ago, and which have never been pronounced unconstitutional, and with which the public are in sympathy fully as much as they are with the federal laws prohibiting counterfeiting.

Again, this wonderful guarantee says:

"We, in turn, promise and guarantee full protection against the state law (which has been declared unconstitutional)," etc.

Now here is another instance of where the manufacturer is endeavoring under false representations to get the retailer to continue a fraud upon the public. They guarantee protection against "the state law which has been declared unconstitutional," knowing fully that the Dairy Union is not prosecuting under that law, and that they cannot be held to the guarantee anyhow. But if they can mislead the retailer and induce him to take chances, then their object will have been attained.

But let the retailer remember this: The law under which prosecutions are being made, provides as a penalty for the third offense, a fine of not less than $500 nor more than $2,000, and not less than one year in the penitentiary. Does the dealer desire to run this risk? Does he desire to risk his liberty, his whole future and reputation upon the powerless postal card guarantee of a maker of an article designed to be used to defraud the public?

It might do to risk a fine, but when one comes to risk a penitentiary sentence, prescribed by law which must be carried out by the court—why, that is different. And the Dairy Union is collecting evidence of second and third offenses right along, with the intention of making examples of some of the more persistent violators of the law.—*Chicago Produce*.

Coming Events.

Georgia Dairymen's Association, Grantville, Ga., Oct. 12, 13, 1899.

THE milk dealers who put faith in the guaranty of the dope dealers that form aldehyde could not be discovered in the milk by the chemist, have had a rude awakening. Five in Beloit, two in Janesville and one in Fond du Lac, all in Wisconsin, have paid twenty-five dollars and costs for using that undiscoverable milk preservative. Do they get this out of the guaranty fund or is it a personal expense?

"Cheese," said some wiseacre long ago, "digests everything but itself." Never, says the editor of the National Druggist, was there a greater error perpetrated by a popular proverb. It aids in the digestion of nothing, and being almost totally indigestible, simply adds another burden to an already overburdened digestive system. The feeling of comfort produced in a person of robust digestive faculties by partaking of a little—a very little—cheese is due entirely to the excitation of the flow of digestive fluid provoked by the indigestion of a completely indigestible substance.

The foregoing is a very successful effort on the part of some one to speak as the fool speaks. Actual digestion experiments made by Profs. Arnold and Engleman years ago, showed that well cured cheese digested easily in seventy minutes. It is the new, unripened cheese that is indigestible.

THE VALUE OF SPECIFIC DAIRY BREEDING.

The following is the monthly record of the milk of the registered two-year-old Jersey heifer, Queen Felch 4th, owned by W. D. Hoard, Fort Atkinson, Wis.

This heifer dropped a fine heifer calf Jan. 6, 1899. She showed wonderful development of udder for so young a cow, and arrangements were made to keep a record of her milk, with a Babcock test of its per cent of butter fat. The record was commenced on the 10th day of January, the heifer then giving an average of 37 pounds of milk a day with a test of 4.7 butter fat. The following is the monthly record in weight of milk up to the 21st day of August:

January,.....712 lbs.
February,.....820 lbs. 10 oz.
March,.....908 lbs. 6 oz.
April,.....804 lbs. 1 oz.
May,.....747 lbs. 14 oz.
June,.....765 lbs. 10 oz.
July,.....549 lbs. 8 oz.
August, (to 23rd) .....351 lbs. 12 oz.

Total milkyield, in a few days over seven months, 5,659 lbs., 13 oz. The average test in butter fat is 5 per cent, or a yield of 282 lbs. of fat, the equivalent of 330 lbs. of butter.

This heifer has at least three months more in which to give milk, and her average yield per day at the present time is between 16 and 17 pounds. We believe the heifer will produce at least 60 pounds of butter before the close of her milking period, which will be the last of October. This will make her record equal nearly 400 pounds of butter. This heifer contains 25 per cent of the blood of the famous old Jersey bull, Ike Felch, which Dr. Linsley, in his "Jersey Cattle of America," includes as one of the five foundation Jersey bulls of America. The mother of this heifer, Queen Felch, was one of the richest butter cows we have ever known, and the heifer shows the inheritance of form and performance strongly. Last year we bred this heifer to her own brother, a son of Queen Felch, and the result was one of the strongest, finest heifer calves we ever raised to a seven months age. The record this heifer is making, together with her rich dairy lines of inheritance, makes it evident to us that it pays to breed specifically for dairy performance.

THE RULE AT THE WORLD'S FAIR.

Mr. Gillett, whose communication is printed in another column, is so much in the habit of not making mistakes, that, after reading what he had written, we turned to the records almost persuaded that we should find them proving our memory at fault as to "the rule at the World's Fair." Moreover, Mr. Gillett is always so courteous in controversies of this character, that we should not have been at all cast down, had the investigation shown that our former position was untenable.

It goes without our saying so, that the citations from Mr. Fuller's report are strictly accurate, but it should not be forgotten that the butter yields reported are simply estimates made by Mr. Fuller, and are wholly independent of any and all rules, whether those adopted by the World's Fair management, or promulgated from any other authoritative source. In making his report to the American Jersey Cattle Club, Mr. Fuller was not unlike too many of our Holstein and other friends, more anxious in his estimates about big figures than strict accuracy; but he was very careful, also, where there was an official record, made up according to the rule adopted by the World's Fair Committee, and approved by Mr. Buchanan, not to claim more than the rule would allow.

Thus, for example, on page 40 of his report, which is the pamphlet cited by Mr. Gillett, he gives the yields of the several herds in the ninety days' test as follows:

	Total fat.	*80 per cent butter*
Jerseys.....	3516.08 lbs.	4274.010 lbs.
Guernseys.....	2784.56 "	3360.431 "
Short-horns	2409.97 "	2890.869 "

In this table, the credit given is for the butter actually made, but reduced for purposes of comparison to the uniform standard of 80% fat. In other words, every eighty pounds of fat, found in the *butter* by the chemist, was credited to the cows as one hundred pounds of butter. Had the rule followed by Mr. Fuller, in estimating the butter that could have been produced from the milk in the cheese test and in the heifer test, which Mr. Gillett refers to as, at least, a partial justification for the methods of our Holstein friends, been adhered to, the following figures would have been given;

	Total fat.	*80 per cent butter (actual.)*	*80 per cent butter (estimated.)*	*Difference.*
	Lbs.	Lbs.	Lbs.	Lbs.
Jerseys	3516.08	4274.010	4395.10	121.090
Guernseys.....	2784.56	3360.431	3480.70	120.269
Short-horns.....	2409.97	2890.869	3012.46	121.591
Totals.....	8710.61	10525.310	10888.26	362.950

These figures show that, according to the rule at the World's Fair, it required nearly eighty-three pounds of fat in the milk to make one hundred pounds butter 80% fat, and it is, therefore, misleading on the part of our Holstein friends, to claim that they are following the World's Fair standard, when they estimate eighty pounds of fat in the *milk* as equivalent to one hundred pounds of butter. They may have other good and sufficient reasons, as stated by Mr. Gillett, for continuing this practice, but we quite agree with him, that it would be much better to report simply the total fat and let every one make estimates therefrom to please himself.

DEATHS IN A SILO.

Three men dead, and a fourth man nearly suffocated in the silo of the Marathon County Asylum, (Wisconsin) August 30th, would seem to be ample justification for the caution so frequently repeated in HOARD'S DAIRYMAN, concerning the dangers attendant upon not providing adequate means for the escape of the carbonic acid gas, resulting from silage fermentation. While this caution has been specifically directed against sinking the pit much below the surface of the ground, the reasons advanced have applied with equal force against any arrangement or construction which did not provide for openings not more than three to five feet above the surface of the silage, so as to allow the free escape of this deadly gas, or at least prevent its accumulation where it would interfere with breathing.

The silo, where this accident occured, was thirty-three feet deep, and was provided with three openings; the filling had been in progress for five days, and had reached to within *eight* feet of the upper opening, after settling over night. The situation when the men reported for duty on the fatal Wednesday morning was:—(1) a mass of freshly cut silage, twenty or more feet in depth, and in the height of its first fermentation; (2) a space of *eight* feet from the bottom of any opening from which the gas could escape, to the top of the silage; (3) weather very warm and contributing to rapid fermentation and development of gas; (4) during the preceding night the gas had accumulated above the silage to such a depth that the instant the men went down the ladder to resume work, they were asphyxiated. Carbonic acid gas is not poisonous, but its effect when inhaled is the same as would result from filling the lungs with water, if that were possible. This gas is not infrequently found in wells, and many accidents have resulted where men have descended into wells, without taking proper caution to ascertain whether gas was present. A lighted lantern, lamp or candle lowered into this gas is instantly extinguished.

That there are not more of these silo accidents is probably due to the fact that so few silos are actually air or water tight. This gas will find its way out of a silo, wherever water could escape, and one or two comparatively small leaks would probably prevent its accumulation. But, on the other hand, the presence of this gas is indirectly essential to the preservation of the silage, for in this way only, can the air be fully excluded, and when air is present, fermentation will go on and destroy the silage. We must have in the first instance a fermentation (heating to about 120°) which produces this carbonic acid gas, and this in turn, if it cannot escape, excludes the air (just as the filling of a bottle with water, drives the air out) and practically arrests further fermentation or decay.

The lesson from this accident is not to condemn or abandon the silo, but simply provide that there shall be an opening, both when putting in and taking out the silage, not more than four or five feet above the surface where the men must stand while at work. In other words, provide that the gas cannot accumulate to such a depth that it can be taken into the lungs.

A Trial Subscription Proves its Value.

A New Jersey Feeding Problem Submitted

ED. HOARD'S DAIRYMAN:—Five months ago a friend put into my hand one of those coin cards for a trial of the DAIRYMAN, which I made use of. Having read it the five months, I find I need it all the time, so you will see enclosed $1.00 for a year's subscription.

We grow corn and rye on farm, which we have been feeding mixed with bran, along with all the green fodder corn they will eat. Cows have fairly good pasture. Now, I want a little assistance. Please give balanced ration from above feeds. If you could substitute something to take place of bran that would be cheaper, why, all the better. Price of bran is $18.40. Have tried gluten, but cows don't seem to like it very well. It seems to have a burnt odor. Can get dried brewers' grains at $14.60. Would they answer in place of bran? We sell the milk.

Farmingdale, N. J. M. C. D.

M. C. D. is not the only trial subscriber who has found HOARD'S DAIRYMAN, a necessity It is not our habit to say much about ou circulation in the editorial columns, but we are assured the returns are coming in very satis factorily, as the result of friendly assistance from our readers, and for which they will please accept our thanks.

Replying to the inquiry submitted, we have to say that when pasture is fairly good, corn and rye make a very satisfactory grain supplement, if one can afford to feed them. Usually, they can be exchanged for some other feeds with a margin of profit. Gluten feed ought not to have a burnt odor, and its presence is doubtless the cause that M. C. D's. cows do not take to it kindly. It is probable however, if not fed too much at first, they may learn to like it. Dried brewers grains, if of good quality, are worth more than bran, but cows do not always eat these with keen relish. They should be well soaked before feeding and some ground corn mixed with them—say, one pound corn to two pounds grains. The amount to be fed must be governed by circumstances; six pounds may suffice for some cows and ten pounds be none too much for others. The true economy of feeding consists in giving each cow all she can make good use of. As long as a cow does not commence to lay on superfluous flesh, one may be quite sure she is not being fed above her capacity.

INQUIRIES AND ANSWERS.

Every inquiry must be signed with the name, Post-office and state of writer. Condense the questions into plain specific inquiry. Be careful to note if your questions have not been answered in replies to others. We are glad to answer all the pertinent questions that we can concerning machinery. Look over our advertising columns and write to the advertisers.

SAND VETCH IN NEW YORK

Referring to the article, "The Sand Vetch" on page 562 of the current volume of the DAIRYMAN, have you any knowledge as to what effect the severe winters of this section would probably have on this plant? What is the market price of the seed?

St. Lawrence, Co., N. Y. SUBSCRIBER.

The sand vetch has not been tried with sufficient thoroughness for us to say what it will do under all conditions of climate, but it is known that it is a valuable drouth resisting plant and would seem to have a very wide adaptability to varying conditions. It has been grown successfully in Dakota and

Minnesota. As the winter is very severe in both these states, it would seem to indicate that it would winter well in New York, more especially as it would have the protection of a heavy snow fall—a condition which does not always prevail in Minnesota. We do not know. Write to dealers in seeds.

A NEW YORK FEEDING PROBLEM.

In our dairy barn we milk fifty-six cows. We feed them in one week, 160 bushels brewers' grains, at 10 cents a bushel; eighty-three barrels starch feed, at 40 cents a barrel; fourteen hundred weight of middlings, at $17 a ton. Each cow receives fifteen pounds a day of timothy and clover mixed, at $10 a ton, and one-half bushel ensilage.

We also have twenty-four head of young stock which we propose to winter on ensilage and oat straw. Can you give us a ration for our milk cows, that will give us as good results as the brewers grains? The dairy is eight miles from Albany, New York, and carting grain twice a week is arduous; all other feed we get in bulk. We are anxious to get the price of feed down and not drop below the average of 475 quarts of milk per day.

We read your paper with great interest, and any suggestion of yours will be highly appreciated. A. H.

Albany, N. Y.

We have no information which enables us to estimate the weight of a bushel of brewers grains (wet) or a barrel of the starch feed. If the grains are of average quality—that is, not too much water in them—their feeding value is about one-fifth that of the dried grains, and the starch feed about one-fourth that of the dried feed. The wet feeds, at the prices named, are probably somewhat cheaper, unless the hauling and waste are items of considerable importance. While we cannot unreservedly, condemn the use of these wet feeds, we never recommend their use, and for the reason that, unless extra caution is observed, they sooner or later foul the premises to such an extent as to seriously injure the milk after it comes from the cow.

Following would be a good average ration;

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
15 lbs. mixed hay.....	12.87	.72	5.94	.24
20 lbs. silage.....	5.28	.26	2.80	.14
3 lbs. dried grains....	2.75	.47	1.09	.15
3 lbs. gluten feed....	2.77	.61	1.45	.09
3 lbs. middlings.....	2.64	.38	1.59	.10
Totals.....	26.31	2.44	12.87	.72

Such a ration should suffice for large cows in full flow of milk.

In place of the grain allowance above indicated, one could expect about same results from five pounds bran and four pounds gluten feed.

The young stock will, no doubt, seem to get along pretty well on the silage and oat straw, but we incline to the opinion that it would be better to include more protein, especially for heifers intended for the dairy, for much the same reason that in rearing a colt for speed, we would give him more protein than if intended for draft purposes.

A NOVA SCOTIA RATION.

My cows are high grade Jerseys and I am sending my milk to a creamery. I will feed each cow per day twenty pounds mixed timothy and clover hay, thirty pounds mangels. Now will you kindly complete for me the cheapest balanced ration from the following feeds. Corn meal at $23.00 per ton, bran at $18.00, cotton seed at $27.00, linseed at $30.00. J. D.

Port Williams, N. S.

For cows of the character named and fresh, or nearly so, we recommend daily allowance as follows:

FORMULA FOR RATION.	Dry Matter.	Digestible Nutrients		
		Protein.	Carbohydrates	Ether Extract
20 lbs. mixed hay....	17.16	.96	7.92	.32
30 lbs. mangels.....	2.73	.33	1 62	.03
5 lbs. bran.....	4.41	.63	1.93	.15
1 lb. cotton seed meal	.92	.37	.17	.09
Totals.....	25.22	2.29	11.64	.59

If it is desirable to increase the allowance for certain animals, take out one pound of bran and gradually increase to two pounds cotton seed meal. Give salt every day.

CALVES FROM A TUBERCULOUS BULL.

I should like to have your veterinary or other expert, state whether in his opinion it is wise to raise stock sired by a bull recently tested for tuburculosis and which was evidently in an advanced stage of the disease when used. The dams are believed to be perfectly sound.

When used, last winter, the bull was in apparently good condition, with the exception of a cough which he had more or less for about a year, but which veterinarians did not think due to the lungs. I presume the usual test would have determined the matter but the best veterinary in this locality did not seem to think it necessary, though requested to make the test. E. E. S.

Lake Co., Ohio.

The probabilities are decidedly in favor of the calves not inheriting the disease, but they should be watched with extreme care and carefully tested with tuberculin, when two or three months old. Moreover, having had such an animal in one's herd, and more especially if he has run with the cows or been watered in the same trough, it would be prudent to have the entire herd tested and all animals that react, carefully separated and kept by themselves, or, if not particularly valuable, at once destroyed.

Perfectly healthy calves have been reared from diseased mothers, by taking them away from the dam at birth and giving them milk from healthy cows or fully pasteurized milk from reacting animals.

DROUTH ON LONG ISLAND.

We are having it very dry now, and we find it very hard to keep our cows from shrinking, as the pastures are very brown.

I am feeding thirty pounds of corn fodder, three pounds of wheat bran, two pounds of ground oats, one pound of corn, two pounds of cotton seed meal.

If you can suggest any alternation that would improve the rations, I would be very thankful. The cows are in about the right flesh. F. M. S.

Oakdale Station, L. I.

The allowance above specified is decidedly deficient in digestible protein, unless the cows get more from the pasture than is probable. It would remedy this defect somewhat to substitute all bran for the corn and oats, or still better, malt sprouts or dried brewers grains.

COW POX.

Last night six of our cows were broken out with the cow pox. I at once gave them a dose of physic, and rubbed on some ointment. I would be very thankful if you would give me a prescription that is a sure and quick cure. Is there anything to keep it from going through the whole herd?

I find your paper a great help, and I don't think any dairyman can afford to be without it. F. M. S.

Oakdale Station, L. I.

Following is the prescription often recommended by Dr. Horne for cow pox: Thoroughly cleanse the teats with Tilden's Bromo Chloralum, one to eight of water. Then when dry anoint all the sores with spermaceti ointment and almond oil, one ounce each, gum myrrh, one dram—to be intimately mixed. Apply twice a day for a while. Give full dose of physic. Be careful of your hands and milk tube. Do not go from an affected cow to another without a very careful washing of the hands with soap and hot water.

PROXIMITY OF DAIRY HOUSE TO STABLE.

Will you please advise us through the columns of your paper how close a dairy house can be built to cow stable, expecting to get best results. Other conditions, viz., ventilation, drainage and cleanliness, are first-class. Manure carted away daily.

Worcester Co., Mass. SUBSCRIBER.

The conditions named, would justify placing the dairy house practically in contact with the stable, but because it is next to impossible to secure these conditions every day, it is only common prudence to provide some intervening space, and we should give more heed to convenience than distance. Would not consider fifteen feet too close for practical safety.

BEST SALT FOR COWS.

We are having some talk around here as to which is the best salt for cows, and so I am going to write to you to find out which is the best. Some say that common rock salt in barrels is best, but I don't. P. L.

Granton, Wis.

Without saying that it is absolutely the "best salt for cows" we prefer the common barrel salt and to give it at least once daily to each cow with her feed. The more we have to do with the cow and feeding of cows, the more are we impressed with the idea that the nearer we approach to the practices which are best for ourselves the better will it be for the cows. Personally, we can see no more reason for putting out a lump of salt for the cow to "lick" as she may be inclined than there is for each man to carry a lump of salt in his pocket for use in a similar way. Similarly, the "salting" of cows once or twice a week, does not appeal to us as the best way. Of course, where it is impossible, or even seriously inconvenient, to give salt with the feed, either of the above methods answers a very good purpose.

SHREDDERS AND SHREDDED FODDER.

I want information on shredders and shredded corn stalks as a cattle food. Am cutting up my corn early to get best results from stalks. Expect to take ears off and shred stalks early. I want to know where to get a machine and what kind and how to treat and feed the shredded product. Please answer in your next issue and oblige.

Galena, Kansas. Dr. J. K. W.

As to the value of shredded fodder the evidence is all in its favor. Where the fodder is dry it can be run from the machine into a mow in the barn and will not take injury, but if not quite dry it is safer to put it under sheds or in narrow stacks.

Our advertising columns give all the information we have in regard to the manufacturers and dealers who supply these machines, any of whom will take pleasure in answering letters of inquiry as to prices and special points of merit. In the absence of the regular shredder, a very good job can be done by putting the corn through the cylinder of a common threshing machine, which will shell off most of the corn and split the stalks fairly well.

MILK TO MAKE A GALLON OF CREAM.

How much 4% milk will it take to make one gallon of 22% cream. J. L.

North Greenfield, Wis.

A gallon of 22% cream will weigh 8.43 pounds, and will contain 1.82 pounds of butterfat. If there were no loss in separating, it would take 46 pounds of 4% milk to make the above cream, but as the loss in separation may be anywhere from .1 to .5%, the actual amount of milk necessary may be from one to ten pounds higher, depending on the quality of separation.

BUTTER RENNET.

The following inquiry has come to the Secretary of the Wiconsin Dairymen's Association:

WISCONSIN DAIRY ASSOCIATION,
Madison, Wis.

GENTLEMEN:—Can you furnish Butter Rennet and at what price? ——— ———.

We omit both signature and post office address, inasmuch as the inquiry was from a dealer in "Dry Goods, Groceries, Drugs and Family Medicines," and was, doubtless, prompted by some of his customers who had received a circular from some source descriptive of wonderful results obtained by using "butter rennet." It is simply a stupendous fraud and humbug. There is no such substance or combination of substances as butter rennet. There are various nostrums that can be used which will help to incorporate more than the legitimate amount of water in butter, but the resulting stuff is of very inferior quality and will soon ruin the reputation of anybody who sells it for butter.

EFFECT OF SEPARATION ON GERMS.

Does running the milk from tuberculosis cows through a separator, destroy all germs which may be in it? W. A. S.

Perry, N. Y.

Running milk through the separator will remove a large number of germs by enclosing them in the material that forms the separator slime, but after all immense numbers are left in the milk itself.

Disease germs are no different from the other varieties in this respect and may, like the other varieties, be partly removed in the slime. If there are any present in the milk that can cause mischief, the separator will not destroy or affect them in any way.

FOR HANDLING MANURE.

Will you let me know what is the cheapest way to handle manure from a stable of twenty cows, which has no cellar. I wish to have the manure retain all its qualities without its becoming an expensive fertilizer through repeated handling. C. S. S.

Boston, Mass.

When other conditions will permit the practice, the cheapest and best way to handle manure is to load it direct from the stable into a Kemp Manure Spreader and haul it directly to the fields to be fertilized. When the construction of the stable will allow the wagon to pass in and out, the manure may be placed immediately in the spreader, but in other cases a carrier or car may be used as shown in the advertisement of D. B. Cherry & Co. on page 603. If by reason of deep snow or otherwise the manure cannot be taken directly to the field, build a manure shed some distance from the stable and dump the contents of the carrier under that. A common wheelbarrow can be used, but such a method would not be as economical as to use a car running on a suspended wire or other track.

A STABLE PLAN.

Could you kindly help me by sending a few plans in your next Journal of a dairy barn to hold about fourteen cows, including a place for feed and hay, as cheap a plan as you can. A. F. J.

Evanston, Ill.

A barn for the stabling and feeding of fourteen cows should be thirty-four feet wide and forty-six feet long, and if other stock or vehicles or machinery is to be housed, as much longer as these additional demands may require. We would arrange the stable about as follows: A central alley or drive way, eight feet wide; on either side, for a distance of thirty-two feet from one end, a gutter twelve inches wide and four inches deep; next to the gutter a platform two inches higher than the central drive way and five feet wide; on this platform build stalls with swinging partitions from three and a half to four feet apart and adopt some one of the various methods of fastening that have been described in these columns.

There will then be left room in one corner for one hospital (box) stall and opposite to it space for a feed and storage room and stairway. Arrange to take hay in at one end (or both ends) from the outside with a horse fork. Provide not less than five good sized windows on each side and two at each end.

FEED AND FAT.

To decide an argument, please answer in your next edition the question, how much, if any, the test of a cow, or the per cent of fat in her milk, can be increased by changing rations? P. W.

Los Angeles, Cal.

A sudden change of feed, whether in character or amount, is very likely to produce a temporary change in the quality of the milk; not directly, but as a result of the effect of the feed upon physical condition or health of the cow. As soon, however, as the cow becomes accustomed to the change in feed, the milk returns to its normal condition. In other words, the feed has no appreciable, direct effect upon the per cent of fat in the milk. This is governed by the inherent temperament, or quality of the cow herself.

Note and Comment.

Drouth in Ohio—Road Dust—Land Plaster—Nitrogen—Nitrogenous Feeds for Calf Raising—Early Filling of Silo—Silo Expansion—Bran and Gluten.

ED. HOARD'S DAIRYMAN:—It is not mentioned by any of the "old timers" who moved in here "right arter the war of '12," that they remember of another so complete a ready made drouth falling out of the sky, and getting so quickly to work, as the one Northern Ohio is now struggling with. It came full sized at the start, and the start was a big all night's rain, and in two days all sign of it was gone and the farmers were saying, how dry it has turned "all t'wunts." Pastures turn brown in a day almost, and dewless and often very cold nights seemed to give the brown a deeper hue. I never knew cows to shrink in milk faster. It was the old story again repeated, nothing handy to feed the cows for a soiling crop, and the cows shrank faster than the milk price went up.

At the creamery here, the shrinkage was over a half, and the rise in milk was only twenty cents per one hundred.

The weather man sends out forecasts to put up the unbrellas, but he only gets dust thrown in his eyes to mock his wisdom, and the flies keep right on torturing the cows, and in the houses getting mixed up with tangle-foot. About the only comforting thing to be gotten out of the drouth is that it is a pretty nice time to lay in a couple of hundred bushels of fine road dust for the stables next winter, and get a fine absorbent, and deodorizer, combined, and not be compelled to go to the plaster trust to get them to trust you for a lot of land plaster that is no better absorbent, and not as good a deodorizer as the dust.

The best thing about the plan is that it gets a fellow to work on the road a day or two and not spend all of the time in getting there, and telling stories and calling it working on the road and then blame bad roads upon the administration and Mark Hanna.

Speaking of absorbents in the stable, causes the inquiry, if your plaster must be bought, why not buy it in the form of acidulated S. C. Rock and get the full value of the purchase in the phosphoric acid, and in addition about one thousand, one hundred pounds or so of the gypsum to the ton thrown in, and then when used in the stable, the nitrogen is caught The manure is strengthened with the phosphoric acid, the element in which it is weak, and better results must follow from the stable combination. There seems to be a growing impression, that the farmer by the better saving of the manure of the barn, and growing more clover and legumes generally—crops direct, and catch—can pretty near supply the fertility wanting, by reinforcing it with the cheaper forms of fertilizers carrying phosphoric acid and potash only, and the use of either road dust, or with phosphoric acid rock, is to secure and deliver to the fields this desired fertility, at the minimum point of cost. The cheapening of dairy products is not alone a question of feed, but is closely allied with the maintenance of fertility, and its application, to the end that maximum crops can be raised and then harvested with the least loss of food material, and utilized with smallest waste of animal force in digestion and assimilation.

***

A little experiment is being made with a calf this summer. While in itself it is not new, it yet illustrates something which too few of us are familiar with: the effect of feeds strongly nitrogenous, upon the growth and make up of the calf and its development. Last spring we took "Slicker's Alaho," some ten weeks old, and placed her in a large, light, box stall, gave her plenty of clean straw bedding, and gave her from then on until now a ration of clover hay and wheat bran, with now and then a handful of oil meal, with plenty of fresh well water at her command. The growth of that calf has been a marvel. The feed has all gone to growth of frame and red meat. She has never showed a sign that she was trying to get fat.

When turned out into the big yard for a run, she has the nerve and strength of a running colt. Now eight months old, she is fast showing up signs of a fine udder, to be; and milk veins to match are easily traceable. It has been a lesson all the time; the sunshine of two large windows into her pen, free air and liberty of motion, it has been a marvel how she has responded to her food in desirable growth, and the small cost to secure it. Two quarts a day of bran has been her daily grain feed, with the clover hay. The estimate is that she will weigh fully seventy-five per cent more than the usual summer calf of her age, with the promise that she will in every respect equal her "Slicker" mother, when she arrives at dairy age.

***

It is a strange condition of affairs in Ohio, when as early as August 24, farmers are filling their silos to save the fodder from further "firing" in the rows, and other things that appear when there is no rain or dew, and the corn is actually "going back," as the farmers express it. North of here on the higher lands, corn is being cut and shocked in the fields, where the owners have no silos, corn not over half grown, neither silked or nearly ma ure. That the corn, cut in this state, has a feeding value equal to its cost, I have grave doubts; but then what will a fellow do? The silage crop about here is the nearest approach to a failure that I have ever seen. Here and there is a fine stand, but these fields are the exception.

There is a lesson being gotten out of it by some farmers, who are building silos as fast as possible, and as soon as they can, will fill the pits with this "spotted" field corn, and try to get all of its food value possible, because they see that if cured and fed in the old way, there will be little feeding value; but harvesting it this way they will make a great saving in food, and have their silos ready for a better crop in 1900, as big crops always grow presidential election years.

I have never known so many silos to be erected in any year in this section, as are being built now. Five men were here in one day to get pointers about silos, and how they were best to build. I think they all decided to erect stave silos, and two will use Page wire fence hoops.

One man, who seemed a little fearful about the strength of the bottom hoop, will use two webs of the fence, by doubling them. Nearly all silos being erected are of the stave pattern. A few will be of the square pattern, with cut corners, as that form will best fit into the barns. Several inquiries about "distributors" for silos prompts this answer.

To my mind the hopper box, with "trousers leg" attachment, is the best of the many ways of getting the silage evenly distributed, and the material well mixed, and that without labor other than "leading" the flexible tube about the silo, until the pit is pretty nearly full, when it will be necessary to do some work with a fork; but then we like to have a small platform built over the silo, and let the silage fall upon this temporary floor, and it is then forked down into the silo, and with a better mixing than one can get who works on a level on the surface of the silage.

If one does not use the hopper plan, the platform under the top of the carrier, so to enable the forker to throw the silage down, is by far a superior way to that of letting the silage fall down unobstructed into the pit, then thrown about. This means at best, that on one side of the silo, the heavier parts of the silage, grain, and the like are thrown, and on the other, the lighter stuff falls, and it takes no end of work to overcome this, by forking material backward and across, and then it will be too much settled in the center, too much of this here and not enough of that, there, and mouldy spots and defective sections will appear here and there as a result; all avoided by either of the two plans indicated above.

***

I notice with interest the purchases of grain at our station for milk making, and see how the farmers always shift back to fine bran, called here "seconds". Last spring there was a slight drift to gluten, and some of the dairy foods warranted (?) to be as good as bran, but this late summer it is all bran again, and not a pound of anything else will be sold here again for months. Most farmers exchange oats for money, and with it buy seconds. Some have their home raised corn, ground cob and all, and mixed with bran for winter feed; but in this locality bran is the best feed for making city milk, especially with the silo men. Whether all of these men take the increased manurial value of the bran added ration into account is doubtful, but those who do, and use absorbents, and draw the stable wastes afield each day, are convinced that this plan of bran buying is a pretty close solution of the fertilizer question, and increasing crops confirm the faith which is within them.

JOHN GOULD.

The Care of Fall Pigs.

ED. HOARD'S DAIRYMAN:—Sows bred last spring, or during early summer, will soon be farrowing now, and should have been getting plenty of green food and exercise, especially during the later weeks of gestation.

For thrifty litters greater dependence can be placed upon fall than upon spring farrowing. There is rarely ever any difficulty in saving a goodly proportion of the young porkers at this season of the year, whereas in early spring mortality frequently occurs with alarming persistency during the first few days.

The reasons for this are not difficult to understand. During summer the sows are allowed the run of the fields to a certain extent; at least they are not closely confined in a filthy sty and fed upon corn, as is so commonly the case in winter. The exercise in the open air is good, the grass and other green food is an excellent diet for the animal at this particular time, and all tends to prepare the way for a thrifty litter.

As soon as the pigs are a few days old the mother should be brought gradually to full feed. She must have plenty of nourishment if she is to supply the needs of a growing family. For this purpose bran, mill feed and ground oats or barley are better than corn, and the latter should be avoided. Corn has its place in the dietary of the hog, but it does not belong to this period of its life. Skim milk made into a thick slop with the ground feed is an excellent factor in promoting a flow of milk. Feed generously. I have no sympathy with the man who scrimps the feed of a sow that is suckling pigs. Growth at this period can be put on very quickly by means of the mother. Allow young pigs to have plenty of exercise. Turn them out for a run every day, if they are not where they can have the freedom of a yard. That disorder which sometimes gives trouble and which is commonly known as "thumps," is caused by lack of exercise, in nine cases out of ten. Lying in the nest all day causes an over production of fat where the dam is generously fed, and the little things soon begin to suffer. If they run and play, as they will when out of doors during the pleasant fall days, they retain their thriftiness and grow in bone and muscle, rather than accumulate so much fat. As soon as possible allow them to eat for themselves. They will get into the trough sooner than might be expected and sweet skim milk, bran, shorts, ground oats are all good promoters of healthy growth.

We wean at about ten weeks, then breed the sows again as soon as possible, usually by the middle of November. This brings the spring farrowing about the middle of March. With care, and due attention to breeding, it is not at all difficult to regulate the farrowing very closely, so that two litters a year can be secured without fail.

After weaning, the pigs should receive very careful attention, until the change has been thoroughly established. Carelessness in the amount and character of the food at this time, may result in a lot of unthrifty, stunted pigs.

Give only what they will eat up clean, before another feeding. Clear the trough of anything remaining therein, and give less next time. It is better to have them hungry, for the next meal, than leave a lot of feed to be nosed over.

Pigs get "cloyed" or off their feed when thus treated, and this gives them a great set back. They should clean the trough out within the time between feedings, yet receive all they will eat. It requires skill and considerable experience to feed a lot of pigs, so as to keep them growing right along from the first day of their lives. It isn't everyone that knows enough to feed a hog, although it is not generally considered as requiring a great degree of intelligence. The main point to be kept in view is to feed of good growing, encouraging food all they will consume, and no more.

Pigs cannot thrive in confinement, unless their quarters are dry. Wet beds breed disease. Straw is plentiful on most farms, yet from sheer shiftlessness the stys are frequently wet and filthy. No animal more thoroughly enjoys a good, clean bed of straw, than the hog. He may be able to endure filth better than some animals, but that is no reason why it should be understood that he prefers it.

Skim milk is an excellent drink for pigs, but it does not alter the fact, that even with this, they require good, pure water to drink. This should be supplied in abundance, at all times.

When about five months old, it is time to begin to prepare the pigs for market. We allow ours to run out day times, even during cold weather, but shut them in a warm house at night. After the fattening begins, it may be better to confine them more closely, but we have had excellent results in allowing exercise right along.

As a finishing feed give all the corn they will eat for six weeks, or thereabout. Watch the market and sell on foot, a much better way than to dress them, unless the number is small. W. C. ROCKWOOD.

City Milk Supply.

ED. HOARD'S DAIRYMAN:—On page 494, I read a communication from Mr. Miller, under the heading of "Nuisances in City Milk Supply." Permit me to say that Mr. Moldenhawer, to my mind, has done every dairy farmer, who wants to follow the onward move of the time, a good service in writing the articles under above heading.

It can clearly be seen from them, how necessary it is to constantly watch and warn the employes to be careful; in fact, it amounts to this: No dairy farmer or dairy dealer who wants to supply good and pure milk, can afford to keep any but intelligent help, that can be depended on to be painstaking in their care of their employer's interests.

This can only be expected when the employer himself is painstaking and sincere in his wish for good and clean milk, and when the help is well paid and treated well. Every up-to-date dairyman should think more of this, and not be satisfied with taking the man that will go for the lowest pay.

The best farmers see and understand this point. For instance, Mr. Bailey, the owner of the celebrated Thorndale Dairy, in Chester, Pa., has supplied his help with a comfortable sitting room, where can be found not alone the latest magazines and farm journals, but also a good assortment of good books. Mr. Bailey knows the value of good and intelligent help, and the men always appreciate such regard for their welfare and comfort. Mr. Editor, I hardly believe that there ever will be cause or need for Mr. Moldenhawer's sharp criticisms in places where both owner and help really know and want to do right.

I wish to remind every dairyman that publicity is, has always been and always will be, one of the surest safeguards against evil of all kinds, and I see no reason why it should not be so in the case of a dairyman

NICE MILK

67 Main St., Cortland, N. Y.

who allows poor and careless handling of a food article.

Mr. Moldenhawer has done the dairy farmers a favor in showing them that a great number of city dairymen are inclined to keep on supplying carelessly handled milk, when they, by a little watchfulness and care, at least, could avoid making the milk worse than when received from the farmer.

I have a number of friends in the medical profession, who are very good patrons of well cared for milk. Many of them read HOARD'S DAIRYMAN as close as they would a medical journal, and every reader of the DAIRYMAN can rest assured that the medical profession and dairymen supplying milk to towns must work together for their mutual benefit.

Dairymen cannot expect to be favored by medical men, unless they both, in their writings and deeds, show that no excuse or inconvenience can keep them from producing the cleanest milk.

Now, Mr. Editor, I have carefully read your valuable and progressive paper for several years, and as far as I can judge, it is much against your ideal view of the dairy question, to rest and be content in saying, "Oh, well, the products from even the worst kept dairy are better handled than the products from bakeries, candy and whisky shops and like places, and why should we keep on reaching after something higher, when the average dairymen already produce a cleaner food article than most other places where food is produced."

This is a very dangerous and hurtful conclusion to be content with, and, Mr. Editor, I have wondered why some of your eminent writers did not answer Mr. Miller, but since this was not the case, I feel it to be my duty to warn the dairymen against such contentment, which is dangerous to the great dairy interest of this country.

The highest ideal is not too high for the dairy industry of a country that ought to be the greatest dairy producing land in the world. Don't let us bother how well or how poor other food products are handled, but follow the highest ideals and the good advice always found in the "DAIRYMAN." When we do that it will soon be found that we have no right to be careless because other people are. JAS. C. JORGENSEN.

Brooklyn, N. Y.

Shredded Ensilage.

ED. HOARD'S DAIRYMAN:—I read the account given by Mr. H. W. Strong, of Washington county, Vermont, in a recent number of the DAIRYMAN, concerning his experiments with shredded ensilage, with a degree of interest, all the greater, because so exactly in accord with the experience I have had myself, along the same lines, during the past two or three years; and it is, of course, always gratifying to know that one's own conclusions in respect to the advantages of a new practice of this kind, are borne out by the opinion of others.

I bought my shredder, also, in the summer of 1896, and have used it for filling my silo ever since—three seasons. The preparation of the ensilage is certainly superior to any I have ever seen put up with a square cut machine; and the same opinion is expressed by farmers generally, in my vicinity, who have been watching my experiments.

Our corn, which is of the Leaming variety, large growth and many large ears, invariably comes out much better than the ensilage of most of my neighbors, which is prepared in the usual way, and the ears of corn, especially, are as sweet and nearly as hard as when put in, while of those put through a cutter, a large per cent are covered with mold. In fact, the ensilage keeps perfectly, and cows eat it greedily, and with practically no waste.

Another gentleman, who lives not far from me, has also been filling his silo with shredded ensilage during the past three years, and is quite as enthusiastic concerning its advantages as I am, and as we are both using the same machine, the "St. Albans," with which Mr. Strong says he has obtained the successful results he describes, the query suggests itself to my mind, whether there may not be something in this question, of the kind of shredder that is employed in making such experiments, that will serve to explain, in some measure, the diversity of opinion one sees expressed in the discussions that take place from time to time, in the papers, upon this subject.

One would not compare the work of a cutter, which cuts pieces three inches in length, with one adjusted to cut one-fourth inch lengths, without making due allowance for this difference in the character of the product; and in the same way, it seems to me, it is essential, in order to obtain a correct solution of this matter, to have it appear what the term "shredding" implies, in respect to fineness of quality, and capacity for close packing.

A great many makes of shredders are now sold—some of them do very fine work; the product of others is as coarse in texture as the fodder put through an ordinary threshing machine; while the work of still another class, is very uneven—some of the fodder being very fine, but with many coarse pieces mixed through it.

The shredder I use makes fodder of a very uniform, fluffy character, and as compared with the ensilage prepared by any machine, cutting into one-half inch lengths, it will pack in the silo fully twenty per cent closer.

Now close packing is a prime condition for the good keeping of ensilage, and it is precisely because ensilage properly shredded, packs closer than any I have ever seen produced by a cutter, that the new method is in my opinion, a decided improvement upon the other.

The feeding, as one writer has said, "is the crucial test," and having seen the silage come out of our silo, year after year, sweeter in flavor and brighter in color, than that taken from neighboring silos, filled according to the usual practice, and seeing it eaten by my cattle with the keenest relish, and practically without any waste whatever, it seems to me the case for shredded ensilage is about as well established as it need be.

Onondago Co., N. Y. W. B. CANDEE.

The Hen on a Vacation.

People take summer vacations for the purpose of recuperating their wasted energies and laying up strength and vitality for the work that is still before them, and nature gives the hen a vacation for the same purpose.

The hen ceases to produce eggs because her system demands a rest. She, herself, hasn't anything to do with it; that is, she does not stop from choice. She cannot cease laying and become broody whenever she chooses, as some appear to think, neither can she continue to lay indefinitely. How foolish, therefore, to say nothing of the cruelty of the practice, to punish hens when they become broody, as so many do, by the inhuman methods resorted to by some, to break up the desire to set.

The kindest, surest, most proper and effective method is to place the hen in a most comfortable coop, on the ground, if possible, in a cool spot, with a small run where she can take exercise in the sunshine, with a dust bath if she wants it, and there feed her well, give her plenty of clean water, sharp grit, and a variety of food, for the more comfortable and happy she is, the sooner will she be ready to go back to her work, and the greater will be her ability to continue it.

The same is true of the moulting season. Moulting usually begins in August or early September, but may be earlier or later, being determined largely by the age of the fowls. It is not a disease, but a natural process by which nature keeps a fowl supplied with feathers, as, if the feathers were not renewed yearly, the natural wear and tear would soon leave the fowl without covering.

Moulting may be continued for three months and usually leaves the fowl, unless very well fed, in a debilitated condition. During the moulting period fowls seem more susceptible to disease. They should, therefore, have especial care during the critical time. Hens usually gain in weight during this process. The manufacture of feathers requires but little carbon, this goes to form fat, but the lack of other necessary ingredients in the food ration may protract the production of feathers, as well as leave the hen weak and debilitated. Lime, phosphoric acid, nitrogen, iron and sulphur are required, and must be supplied in the food.

The rations should consist of a generous supply of bone meal, charcoal, meat and vegetables. A pinch of red pepper or a little tincture of iron given in the drinking water is an excellent tonic. Sunflower seeds are said to loosen the feathers, and give gloss and brilliancy to the new growth. Hemp seed is recommended for the same purpose. An excellent grain ration consists of ground oats and bran, equal parts, and to each quart of this, one gill of linseed meal. This may be given twice daily, allowing the hens all they will eat. Give, also, a regular ration of gound meat and green bone. Cut green bone may be fed at the rate of one ounce per hen per day, given in the soft feed.

A Charl tte, N. C., poultry keeper has recently hit upon a novel and inexpensive method of supplying his fowls—growing chicks, I believe—with insect food, which might answer very well for a change of diet for moulting hens. He takes ten or twelve pounds of cotton seed meal, wets it thoroughly and puts it into a ridge, about four feet long, in the chicken yard. A couple of boards are laid over it to keep the chicks from scratching it about. In from three to five days it is full of maggots. He then uncovers it gradually, and the chicks find the maggots. Other materials, as corn meal, bran and cotton seed meal, or flax seed meal moistened with molasses water, may be used. This method would be practicable only during the hot weather, but certainly is one of the easiest and cheapest methods of obtainable insect food yet brought forward by any one.—*Northwestern Agriculturist.*

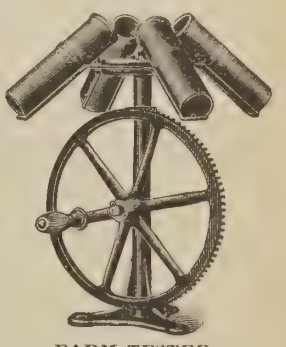
Keep Coughing

We know of nothing better to tear the lining of your throat and lungs. It is better than wet feet to cause bronchitis and pneumonia. Only keep it up long enough and you will succeed in reducing your weight, losing your appetite, bringing on a slow fever and making everything exactly right for the germs of consumption.

Stop coughing and you will get well.

Ayer's Cherry Pectoral

cures coughs of every kind. An ordinary cough disappears in a single night. The racking coughs of bronchitis are soon completely mastered. And, if not too far along, the coughs of consumption are completely cured.



Ask your druggist for one of

Dr. Ayer's Cherry Pectoral Plaster.

It will aid the action of the Cherry Pectoral.

If you have any complaint whatever and desire the best medical advice you can possibly obtain, write us freely. You will receive a prompt reply that may be of great value to you. Address,
DR. J. C. AYER, Lowell, Mass.

Be Careful

FARM TESTER.

To read article on page 488, issue of Aug 4, HOARD'S DAIRYMAN, regarding the Use of Babcock Testers in Cheese Factories.

We were the first manufacturers to make a tester in which to test milk after the method devised by Dr. Babcock, and we have always retained the first place in the list of manufacturers. The Farm Style, Factory Hand Style or Factory Motor Tester are the best made. Full descriptive catalogue, with directions for operating, free.

PLAIN TALKS ON BACTERIA AS APPLIED TO FARM PROBLEMS.

[By Prof. H. L. Russell.]

Second Series, No. XXIV.

MANURES FROM A BACTERIOLOGICAL POINT OF VIEW.

Manure, as commonly used, means the excrements of animal life. These include not only the liquid excretions from the body, the urine, but the undigested remains of the food which is passed off from the intestine. The urine is especially rich in urea, a somewhat complex nitrogenous body excreted from the kidneys. As a plant food, however, urea has no value; in fact, it acts as a poison to protoplasm. But it is capable of being converted into a form that is assimilable by plant life. The solid excreta from the intestine is not so rich in nitrogen, but it also contains a certain amount of plant food which is not available until transformed. The transforming forces that take these animal wastes and convert them into food that will sustain another crop of green plants, are the bacteria. Where do they come from? A bacteriological examination of carefully voided urine shows that it is not at all rich in bacterial life. It, like most of the secretions of the healthy body, is practically sterile, but if urine is allowed to stand for several days after it is voided, a marked change occurs. The clear fluid becomes cloudy and sooner or later an ammoniacal odor is evident. This has been occasioned by the development of certain bacteria that have the power of growing in this quite acid solution and transforming the urea into ammonium carbonate. As this substance is volatile, it passes off readily into the air unless something is present with which it can unite. Even in the form of carbonate of ammonia, the nitrogen is not yet available for plant food. It must be acted upon still farther, undergoing a process known as nitrification, which subject will be considered later.

Although the urine is poor in bacterial life when it is excreted, the wastes from the intestines are far from being in a similar condition. The processes of digestion that go on in the animal body are very complex. The food is first rendered soluble so that it may be absorbed; then it is digested by the different tissues of the body and appropriated into the substance of the individual cells. Much, however, of the food is of no use to the animal body and could not be utilized on account of its insoluble nature. Such material is cast off in the excreta, but with it comes myriads of bacterial germs that have been harbored in the intestine. In this habitat, special forms are able to thrive on the partially digested food. These work over and break down in part the material that cannot be utilized by the animal; but although somewhat broken down when evacuated, it is still far from being of any fertilizing value as a food for growing crops.

RIPENING OF MANURE.

This fact is, of course, well known. Green manure must first undergo a long series of changes before it can be appropriated by the green plant and built up into stalk and ear. But from the time it is thrown out of the animal these millions of organisms are busy at work, changing the insoluble matter into soluble form, transforming it from the complex state into a simpler but more stable condition. In fact, the ripening process which is so essential in preparing it for further use, is merely a continuation of the changes that are inaugurated in the animal. Of course the kind of organism that is at work on this refuse pile does not remain the same throughout the whole process. As one kind of fermentation is followed by another, so one kind of bacteria succeeds another. We may imagine the process like that which is going on in cleaning up of the debris of a great ruin. One shift of laborers follow another; one working on the iron work, another on the wood work; so these different classes of bacteria pick out the peculiar substances that are best adapted for their purpose, leaving the refuse to be worked over by some other kinds.

KIND OF FERMENTATION GOVERNED BY EXTERNAL CONDITIONS.

The type of fermentation that goes on in the ripening heap of manure is determined to a large extent by the influence of external conditions. In the manure heap, nearly all varieties of germs are represented, at least so far as the different types of activity are concerned; but whether one or the other gains the ascendancy depends upon whether abundant oxygen is present, copious supplies of moisture and the like. In the outer part of the manure heap, the type of ferment action is such as can go on where the free oxygen is present. These oxidation processes reduce the combined substances that are locked up in the raw manure into simpler forms, some of which are gaseous and therefore go off into the air.

For this reason, if a manure heap is loosely built up, the character of fermentation is aerobic and intense. The result of this is to cause the loss of valuable fertilizing properties. A well compacted heap retards this oxygen fermentation and so preserves the organic matter from too rapid change.

The type of fermentation that goes on in the middle of the heap is quite different from that on the exterior. Here the atmospheric oxygen is greatly diminished in supply, or entirely lacking, and the result is that only those bacteria can grow that can develop in an oxygen-free atmosphere. These forms, known as anaerobes, are able to break down the organic matter, but they form far different products than are produced where oxygen supply abounds.

The type of bacterial activity is also greatly modified by the presence of moisture. The dry dung of horses undergoes intense fermentation, and is therefore subject to "fire-fanging," a condition that destroys in large part its fertilizing quality. This can be prevented by mixing this kind of manure with that of other kinds of animals that is richer in water. Under these conditions, the aerobic bacteria are somewhat repressed and the intense activity is minimized.

The losses that arise from too intense and rapid fermentation are confined mainly to the nitrogen and the humus-forming elements. The rapid formation of ammonia due to the decomposition of the organic matter accounts for the loss of nitrogen, while the organic matter is also too completely burnt by this same process, thus rendering it of less value for the formation of humus.

The losses that actually occur on farms are not entirely due to these biological processes. One of the most prominent ways in which loss in fertility occurs is that due to leaching. This is caused by exposure of the manure to the action of wind and rain. The soluble elements in this way leach out. This process is itself a physical one, but back of this is a biological cause, for if no bacteria were present, no ripening changes would occur, and as a consequence the insoluble organic matter would not become soluble and therefore could not leach away.

To these tiny, microscopic forms then the farm is much indebted, for were it not for these organisms, the fertility removed in the crop year by year would soon become depleted and unless restored by these agencies would render agriculture unprofitable.

The Rule at the World's Fair.

Mr. Gillett's Views.

Ed. Hoard's Dairyman:—I have noted from time to time in your publication, in referring to the plan used by the Holstein-Friesian Association for determining the amount of butter from a given amount of fat, (the 80 % basis) that you criticise the Association and that in your issue of September first you state: "This was not as they seem to claim, the rule at the World's Fair."

Permit me to say the H. F. Association does not hesitate nor do I hesitate to say that this was the very basis used at the World's Fair in tests where the amount of butter was estimated from the amount of fat produced, or in other words in tests where the churn was not used.

To substantiate this claim I refer you to the report of V. E. Fuller, and on page 21 of this report, we find the following in refering to Test No. 4, for two year-old heifers: "The churning in the dairy was dispensed with; the fat was ascertained by the Babcock oil test * * * and the butter was estimated therefrom, on a basis of 80 % oil in the butter."

Now, let us turn to page 50 of this report and note in the table that the Jersey heifers produced a total of 155.38 pounds of fat and are credited with 194.226 pounds of butter. If we take our pencil and divide this amount of fat by 80, we will find the same figures for the amount of estimated butter, which is identical with the plan used by our Association to-day. Let us farther turn to page 34 of the same report and note in the table showing the estimated butter in test No. 1, the cheese test, a total of 602.01 pounds of fat. Dividing this amount by 80 we have 752.5+ pounds estimated butter, exactly the figures given in the third column and reported by the chairman of the testing committee, as being the amount of butter produced.

It was upon this very basis that the Holstein people have been working and I cannot understand the force of your statement that "it was not a rule at the World's Fair." Indeed it appears to me very plain that it was a rule at the World's Fair and under the light of these facts I think we are justified in so stating that such is the case.

I make no claim that this is the correct basis for determining the amount of butter from the fat, as this is not the point. The point, is was the 80% method a rule at this fair.

As this question has never had an explanation in your paper, I wish to briefly outline how our association came to adopt the 80% method. We were I believe, the first association to recognize the Babcock test for determining the amount of butter our cows produced. We adopted this test prior to the World's Fair, and at that time estimated the amount of butter on the basis of adding one-fifth to the fat. Then came the World's Fair; and in the tests mentioned from the fact that the 80% method was used it was thought we were wrong, hence the change to the present plan. Sometime later the Associated Chemists agreed upon the plan of adding one-sixth to the fat for determining the amount of butter.

During the interim we had been accepting cows for admission to Advanced Registry on the 80% plan, supposing this would hold for all time, and be generally accepted as a fair and equitable way of apportionment of butter from fat. To change at this time, would in some cases require cows to make a greater yield of fat for admittance to Advanced Registry, than was required of those admitted on the 80% plan for determining the butter. In fact, some that were admitted would by adding one-sixth to the fat, fail to reach the requirement, but at the same time are accepted and registered.

I know of no other association that is using the plan of adding one sixth nor can I find my estimate at the World's Fair worked out on this basis. I believe the Jersey Cattle Club has adopted the plan of adding one fifth to fat and personally I believe this is nearer correct than either the eighty per cent or the plan of adding one sixth. I believe, with the separator and the Babcock test, it is both possible and practicable to retain all the fat, in carefully conducted tests of single cows, fed and handled for great yields, though it may not be so in creameries where a large quantity of milk is handled.

In truth I think our association was practically correct before it made the change to conform to the plan used at the World's Fair, but in any event let me assure you that we are not using the present plan with the intent of making our cows appear better than they really are nor with a view of deceiving any one. In all reports of tests the association states the amount of butter fat produced, or if reporting the finished product the basis of calculation, and the reader can take this amount of fat and figure out as little or as much finished butter therefrom as he sees fit.

Certainly there is no injustice in this, but it appears to me there is an injustice to he Holstein fraternity when one of the leading dairy papers comes out boldly with the statement that there was no such rule at the World's Fair for the expression of fat yields in terms of butter. First it conveys the idea to its readers that our people wish, from a basis of false claims, to mislead the public and second it makes the butter fat yields at the World's Fair in those tests where the churn was not the guide, appear larger than they really are.

I trust the time will come and I believe it is near at hand when the amount of fat only will be stated in reporting tests of dairy cows. There is a diversity of opinion as to the

Prepare for Winter.

Now is the time to think about keeping your stock warm during the coming winter. Before cold weather sets in look over your out buildings and see if there are any leaky roofs, any shingles or clapboards coming off, or any cracks that need stopping up to make the buildings warm.

It is poor economy to have cows and horses sleep cold in the winter, and every farmer knows how much more profiable hens are, and how much faster the chickens grow if they are kept warm.

If you will accept a suggestion from us, of which the editor of this paper will approve, you can fix up your old outbuildings, prevent leaky roofs, make warm your sheds, barns, hen houses, hot beds or green houses at very little expense.

Go to your nearest hardware dealer and get a roll of **Neponset Red Rope Roofing,** which is made for any outside covering, and is

postively water-proof, wind-proof, and frost-proof. There are five hundred square feet in each roll, and it will only cost you $5.00 including the necessary nails and tin caps.

Don't confound **Neponset Roofing** with common tar paper, which, when exposed to the weather will crack, crumble and quickly rot away.

Tar paper was all right for your grandfathers, but in this age of advancement a covering which is very much more durable and economical is required, and that is **Neponset.** It is cheaper and better than shingles; it takes the place of shingles or clapboards on outhouses, and back-plaster in dwellings. Any one can put it on and it will last for years.

If you would like to have a sample of this paper and full particulars before you buy, send a postal card to **F. W. Bird & Son, East Walpole, Mass.,** and they will send it to you by return mail free.

amount of butter that should be credited the cow from a given amount of fat and by reporting the fat alone we leave every man to weigh this amount of butter according to his own estimate, guided by his ability to convert the same into butter without loses occuring through skimming and churning processes.

It is equally as true to say from a given amount of fat we have so much butter, 80% fat, as it is to say we have a different quantity by adding one-fifth or one-sixth. The fact is, we have butter from neither, it is only an expression of butter; an equivalent under certain conditions of the finished product and in cases where the churn is used perhaps none would be absolutely accurate but so long as the facts are stated, I fail to to see any injustice or that it can be in any way misleading.

Men were born to disagree and it is perhaps better that such is the case but it does not follow from this that they should have any less respect for one another on account of a difference of opinion and I therefore trust you will accept this in the same kind spirit that prompts it. W. J. GILLETT,

Rosendale, Wis.

Our Special Elgin Letter.

ED. HOARD'S DAIRYMAN:—The Board of Trade met on Tuesday this week, Monday being a holiday. But 6,660 pounds of butter were placed on sale and all was sold at 21 cents. The market was declared steady at that figure. The sales reported were:

	Pounds.	*Price.*
Darinda	3,000	21
McConnell	1,140	21
Red Clover	2,520	21
Total	6,660	

The sales for the corresponding week of he three preceding years were as follows:

Sept. 5, '98, 7,800 pounds of butter sold at 18c.
Sept. 6, '97, 18,000 pounds of butter sold at 17c.
Sept. 7, '96, 87,120 pounds of butter sold at 15@16c

The New York market Monday was reported steady at 21 cents. H. C. B.

Elgin, Ill., Sept. 5, 1899.

DAIRY MARKETS.

ELGIN, Ill., Sept. 5—There were 111 tubs offered; all sold at 21 cents; committee reported steady; 21 cents.

PLYMOUTH, Wis., Sept. 5—Sales to-day, 1,150 Twins at 10½ cents; 400 Twins at 10¾ cents, and 1,125 Americas at 10¾ cents; market active.

SHEBOYGAN, Wis., Aug. 30.—The offerings on the Call board to-day were 1,310 boxes of cheese, all but 115 of which were sold as follows: 80 cases Young Americas at 10⅞ cents; 243 at 10¾ cents; 337 at 10½ cents; 128 Twins at 10⅝ cents; 38 at 10½ cents, and 369 Daisies at 10½ cents; market active.

MANITOWOC, Wis., Aug. 30.—Offerings of cheese at the Dairy board to-day were: 1,300 boxes Daisies, 150 boxes Twins, 800 boxes Young Americas. All offerings sold; Daisies at 9¾ cents, Twins at 9¾ cents, Young Americans at 10 cents.

FOND DU LAC, Wis., Sept. 4—Cheese—Offerings 743 Twins and 500 Daisies; market fairly active at 10¾c for Twins.

MUSCODA, Wis., Sept. 4—Cheese—Offerings to-day 1,263 boxes Twins; market firm; all sold; carlots 10⅝c; small lots 10 7-16c.

CHICAGO, Ill,, Sept. 4—Butter—Creamery, extras, 20c; firsts, 18@18½c; seconds, 15½@16½c; dairies, selections, 17c: No. 1, 14c; No. 2, 13c; extra ladle, 13½@14c.

Cheese—Full cream, Twins, new good to choice 10½@10¾c. Young America, 11@11¼c; Swiss, 9@11c: Limburger, 8@9c; Bricks, 9@10c.

Eggs—Fresh at mark, cases returned, sold at 12c, loss off; cases returned, 14@14½c.

Cattle—Receipts were estimated early at 17,500 and later at 16,500. The general market opened strong to a shade higher, but closed weak at last week s closing prices. Trade was active and a good clearance was made. A load of 1,456-lb.steers sold at $6.60, which was the top a year ago. Three loads averaging1,204 lbs. sold at $6.50,and two loads of 4-year-old steers averaging 1,714 lbs. at $6.40. Corn-fed westerns sold at $4.50@6.30. Seven loads of 1,313@1,345-lb. grass western rangers, direct from Dakota, sold at $5.35@5.40. Most of the grass westerns sold at $4.40@4.75, with a train load at $5.@5.15. Grass Texas steers sold at $3.b5@4.12½. Most of the corn-fed native steers sold at $5.60@6.25. Native cows and heifer sold a shade higher.

NEW YORK MARKET.

NEW YORK, Sept. 2—Butter—Receipts for the week, 37,751 packages. Exports for the week, 19,086 packages.

The market is steady and strong at last week's quotations. Most of the exports were goods bought several weeks ago at prices ranging from 18@20c, and held in cold storage here because there was no freight room until this week. Local trade is buying only enough fancy, fresh butter to supply their immediate wants, but so little of the arrivals are running extra in quality, that full prices have been obtained. Exporters are taking some of the finest June creameries at 20@20½c, and are reported as buying large lines of ladle butter at 14@16c. New York State dairy is scarce and wanted. We quote:

Creamery, extra, 21c; medium, 19@20c; poor, 15@17c. Dairy, extra, 19@20c; medium, 16@18c; poor, 14@15c. Ladle, extra, 15½@16c; medium, 14½@15c; poor, 12½@13½c.

Cheese—Receipts for the week, 39,000 boxes. Exports for the week, 11,660 boxes.

Our market don't keep up with sales reported at interior points. Exporters took some of the finest large cheese at 10¾c@11c, and home trade bought liberally of small sizes at 11@11¼c with several sales reported fancy western New York cheese at 11⅜c. All under grade cheese are in light supply and wanted at full prices. We quote:

Full Cream, large, extra, 11c; medium, 10@10½c; poor, 7@9c. Small, extra, 11¼@11½c; medium, 10¾@11c; poor, 7@9c. Part Skimmed, extra, 10@10½c; medium, 9@9½c; poor, 6@7c.

Eggs—Receipts for the week, 59,447 cases. Finest marks, fresh stock, are in ready demand at our advanced quotations. fair to ordinaty lots slow and irregular in prices.

N. Y. State & Penn. best marks, per dozen, 18@20c; Western & Northern, 16½@17c; other sections, fair to good, 12½@16c. DAVID W. LEWIS.

177 Chambers St.

BALTIMORE MAKKET.

BALTIMORE, Aug. 31.—Butter—The usual quantity of separator creamery has reached this market this week, and without any particular display of energy directed toward accomplishing the result, likewise without any unusual movements after the efforts were rewarded by the sales, somehow the bulk of the arrivals have found buyers who wanted them for immediate use, and so they have effectually disappeared; the other part, distinguished from the bulk by reason of defects in grading, has given the salesmen more concern, because, if experience has taught anything it would be that it has not been profitable to "go against" the street on the question of values, where faulty creameries are the subject of bargain and sale; but on the other hand the firm feeling in the west with respect to the future renders him undecided as to the best thing to be done at this time, notwithstanding the experience of the many previous years. Gathered cream creamery products are now about normal in quantity—the receipts, this week, show no further falling off compared to last week—and are fairly satisfactory in quality. Imitation creamery is very scarce, so is also ladle, and while the grading is by no means high, yet the demand is urgent enough to encourage receivers to insist upon getting full prices. Store packed is in light receipt with active demand.

Creamery Separator, extras, per lb, 20½@21; firsts, 19½@20; seconds, 18@19; gathered cream, extras, 18½@19; firsts, 17@18; seconds, 16; Ohio, extras, 18½@19; firsts, 17@18; seconds, 16; imitation, extras, 16@17; firsts, 15; seconds. 14; Iowa & N. W. Ladle, extras, 15; firsts, 14; seconds, 13: Ohio & Indiana Ladle, extras, 15; firsts, 14; seconds, 13; Ohio Storepacked, extras, 13; firsts, 12@12½; W. Va., extras, 13; firsts, 12@12½; creamery blocks,(2 lbs.) extras, 23; firsts, 22; seconds, 21; creamery prints, (½ lb.) extras, 23; firsts, 22; seconds, 21; Md., Va. & Penna., prints, extras, 19@20; firsts, 18; seconds, 16@17.

Cheese—Receipts of cheese fair; demand good; market firm.

New York State Cheddars, fine, 10¾@11; choice, 10¼@10½; fair, 9¼@9½; Flats, fine, 11@11¼; choice, 10½@10¾; fair, 9½@10; Small, fine, 11¼@11½; choice, 10¾@11; fair, 10¼@10½; Ohio Flats, fine, 10¼@10½; choice, 9¾@10: fair, 9¼@9½; Ohio Picnic, fine, 10½@10¾; choice, 10@10¼; fair, 9½@0¾; Swiss cheese, fine, 12@13; choice, 11@11½; fair, 10@10½.

Eggs—The receipts of choice fresh eggs so far this week have been exceedingly light, while the demand for this kind has been quite active, consequently we write our market in good shape and bare of choice stock. Prices are firm at 16c, and the tendency is for still higher prices.

301 Exchange Place. G. M. LAMB & BRO.

LIVERPOOL, Sept. 4—Cheese--American finest white, 53s; American finest colored, 54s.

MANCHESTER, ENGLAND, MARKET.

MANCHESTER, Aug. 19—Copenhagen has again advanced the official quotation four kroner this week, showing current rates 20% over the corresponding week of last year. Of this advance 15% of it has been put on during the past four weeks apart from over-prices paid for special dairies. These continued advances have been caused by the recent hot and dry weather scorching the pastures. Up to now the consumptive demand has absorbed the supply at these continually rising figures, how long it will continue to do so is a difficult question to answer. The import into the United Kingdom to the end of July shows an increase of 4,722 tons of butter compared with the same period of 1898. Of this increase Denmark has contributed 1,169 tons, and compared with 1887 as much as 4,202 tons. Sweden, on the other hand,though extending dairying considerably has exported 1,102 tons less owing to increased home consumption through general manufacturing prosperity. The other countries most prominent in this increase are Australasia, Canada, and the United States. Ireland is doing her share in improved dairying, Centrifugal Creameries now number nearly 400 on the Danish system, and with the newest Swedish Separators, whilst the outpour of factory butters is assuming very large dimensions. Shipments at sea for next markets from Denmark and Sweden are cabled 19,066 casks, being 636 less than the previous week, and 1,966 fins, or 277 casks more. Cooler temperature begins to prevail with rain.

Margarine arrivals—*Via* Hull, 11,650 packages. *Via* Grimsby, 4,717 packages. DOWDALL BROS.

READING NOTICES.

All Reading Notices under this head are at the rate of 25 cents per line.

Wanted—To build, buy or rent creamery in good location. References furnished. ED. SEAMAN, Blue Mouud, Wis.

Wanted—A position by a first-class buttermaker and creamery manager. Twenty years' experience. Best of references. Married. Address C., care HOARD'S DAIRYMAN. 30-2

Wanted—A man with family, honest and industrious, to take charge of a 250-acre farm, well improved, with dairy attached, for an interest in profits. A fine opening for the right man. Must come well recommended. Good market for produce. Can sell any quantity of sweet milk at 20c gal., buttermilk 10c per gal., and butter 25c per pound. For particulars address J. O. THURSTON, Bartlett, Tenn.

Wanted—Married man to take charge of 25 cow dairy. S. READ, Bristol, Tenn. 30-2

Wanted—To rent to reliable person at once, herd with pasture and stables, 3 miles from Augusta, Ga. Address J. M. McKIS, Augusta, Ga.

For Sale—2nd hand U. S. cream separator, No. 5. G. W. SHAW, Allen's Falls, N. Y. 30-2

Keystone Corn Husker and Fodder Shredder for sale, in perfect repair, at greatly reduced price. Apply FONT GROVE FARM, near Slingerlands, Albany Co., N. Y.

1899 the Greatest of "Alpha" Disc Years.

For eight years past every year has been an "Alpha disc year in the sale of cream separators, their success being greater from year to year and greatest of all in 1899.

Beginning with a relatively small sale in 1890, the superiority of the "Alpha" disc system was so great as to achieve instant success. The sale in 1891 was double that of 1890 and the sale of "Alpha" disc machines has thus continued to virtually double itself from year to year, in the Factory and Dairy sizes combined.

The recognized supremacy of the "Alpha" disc system is now so great in Factory separators that the purchase of De Laval machines in 1899 has been almost universal, exceeding 95 per cent of the total sales in the West, and 85 per cent in the East. In the Farm or dairy sizes of machines the users of such separators have not yet come to so well understand the differences between separators, but are rapidly acquiring this knowledge from practical experience, and the same percentages nearly hold good, and within another year or two will undoubtedly do so.

Users of separators—whether big or little—have come to understand that **The "Alpha" Discs are literally the heart and soul of a perfect cream separator** and that the all around efficiency and general practicability of the "Alpha" disc machine is simply unapproachable by anything else that can be put together in the shape of a cream separator, regardless of price, clap-trap claims of would-be competitors and every other conceivable consideration.

The differences in principle and construction between the "Alpha" and other separators are fully illustrated and made plain to every one in the De Laval catalogues—Creamery or Dairy—which may be readily had for the asking.

The De Laval Separator Company,

WESTERN OFFICES: Randolph & Canal Sts., CHICAGO.
GENERAL OFFICES: 74 Cortlandt Street, NEW YORK.
BRANCH OFFICES: 1102 Arch Street, PHILADELPHIA.

Wanted—A practical and reliable dairyman to take charge of my dairy farm, and will rent for a term of years to right party. Farm has all the modern improvements, consisting of 2 silos, stone floors (700 yds.), system of waterworks, brick creamery and a private market for all the butter at 25c in Sioux City. Cream separator and a market for cream. My farm of 200 acres lies 6¾ miles south of Sioux City, on the Missouri bottom lands. We have two cottages for help and can handle 40 cows with ease. I wish to rent as my children are too small to assist me in care of farm. A. J. WESTFALL, Sergeants Bluffs, Iowa. 30-2

Guernseys at Auction—I will sell at Public Auction on my farm near Fort Atkinson, Wis., on September 20th, commencing at 10 a. m., 32 head of high grade and registered Guernseys, consisting of 4 registered cows, 8 high grade cows, 10 two-year-old high grades, half coming fresh this fall, 10 grade calves from 1 month to 11 months old, 1 registered bull calf 6 months old, Springer Jr., No. 3926, the head of this herd, will also be sold. This is an excellent lot of well bred grades and full bloods and offers exceptional chance to secure good stock. GEO. D. TELFER. 30-2

Public Sale of High Grade Jerseys—I will sell on Sept. 14th, on my farm near Fort Atkinson, Wis., 32 head of high grade Jerseys, consisting of 26 milch cows, 6 two-year-old heifers and 1 full blood Jersey bull eligible to registry. This is a choice herd bred for butter producers, and offers buyers good chance for rare grade stock at their own prices. W. E. SOWLE.

Wanted—Married man and wife. Man must be thoroughly experienced in care, feeding and milking of high class Jersey cows and other stock, must understand separator and Babcock test. Woman must take charge of cream and dairy utensils and make butter. Must board themselves. Address BOX 173, North Greenfield, Wis. 25-5

For Sale—25 choice milch cows, 3 to 9 years of age, and 15 heifers aged from 15 to 20 months, all high grade Guernseys. Also a full-blood Guernsey bull 2 years old for sale. A. L. STRONG, Elkorn, Wis. 29 2

Wanted—to hire a good substantial and reliable farm hand. Middle aged and single. J. B. SHATTUCK, Cherry Creek, N. Y. 28-3

Wanted—Man to take charge of Jersey dairy farm. Prefer a married man from dairy school. Must be well recommended and a worker. I do the kid glove part. State wages. GEO. A. BUCKSTAFF, Oshkosh, Wis. 29-2

Tamworths, ready to wean, $10 each, or $12.50 delivered. Hermanville Farm, P. E. I., Canada 32-52

Wanted—A competent person, with about $1,500, to buy an interest in and run an established dairy, adjoining the city of Baird, Texas. Interest to be only in live stock and dairy outfit and not in the land, of which there is 1000 acres, 200 acres in cultivation and 800 acres pasture, all of which will be rented reasonably. All improvements necessary for first-class dairy. Spring, spring-house, 400-ton silo, barns, corrals, etc. Regular sale for creamery butter, 25c year round; milk 20c per gal No other dairy. Address at once. W. C. POWELL, Baird, Tex. 29-3

For Sale—An almost new 16 inch Ohio feed cutter with 22 foot carrier. Used 10 days filling silo. Price $62 for outfit. Only reason for selling is we have a larger one of same make. GEO. C, HILL & SON, Rosendale, Wis. 29-2

Wanted—A thoroughly competent and experienced man to work on a dairy farm. Must understand care and feeding of dairy cows. Also must understand steam and care of separator and all modern dairy utensils. Graduate of some dairy school perferred. For particulars address A. J. DAUGHERTY, Streator, Ill. 29-tf

Wanted—Two married men of small family, to work on dairy farm Must be sober, willing and industrious and thorough milkers. Men whose wives will milk, perferred. Steady employment to right parties. Must board themselves. Address P. O. Box 173, North Greenfield, Wis. 29-2

INFORMATION WANTED.

It is impossible to get too much information regarding the breeding and testing of the dairy cow. Every year brings a new lot of dairymen, and, also, a new crop of calves, which should be fed, milked and bred in a manner to give the largest returns. In many cases the returns will be satisfactory; others, through want of the right kind of knowledge, have not made the success which they anticipated. From both classes much valuable information can be derived; to know where and how one has failed is as valuable, as to know why another was successful. We shall be glad, therefore, if a number of the readers of the DAIRYMAN, and the larger the better, would send us answers to the following questions, taking care to give their failures as well as successes:

1. Have you tested your herd, by weighing the milk and the Babcock test, to find which were the poor cows?
2. How long did you test, and how many did you reject? (Give the whole number of the herd at the beginning of the test.)
3. Is it much trouble or expense to do this, and what plan did you pursue?
4. Have you ever taken a herd of common cows, placed a registered sire at their head, and so kept up the system, until you brought out of it a herd of grade cows?
5. What was the breed you selected, and how much more butter, cheese or milk did you get from the daughters than the original mothers?
6. Would you advise changing breeds, one after another, or breeding right along in the same line?
7. Have you ever bred the daughters back to their own sires, and if so, what was the effect on the health and dairy capacity of the grand daughters?

NOTE—We want as many short, brief answers to the foregoing, from as many different men as possible. Make the answer to each question short as is possible; simply state the facts, not opinions. Do not worry about the style or grammar of your statement. Answer each question by number, and state your experience.

BUTTER AND CHEESE EXPORTS.

A marked increase in the exports of butter this season may, in some measure, be due to the efforts of Secretary Wilson, of the Agricultural Department, to improve the quality. But the principal reason is probably the decrease in the available supply from Denmark and other countries in Northern Europe. During July, 20,807 packages of butter were exported, as compared with 2,587 packages in July last year. But in the corresponding month of 1897 there were 36,042 packages exported. For the week ending last Saturday 35,125 packages were exported from Montreal, more in one week than the United States exports in a month. This is due to the bad reputation United States butter obtained in Europe by reason of the large exports of oleomargarine and other imitations as "real creamery butter."

There never was a better illustration of the wisdom of the old saying that "honesty is the best policy" than in the experience of the United States in the export trade in butter and cheese. Formerly we did a large export trade in these goods—many times greater than that of Canada. Now Canada greatly exceeds the United States in the exports of cheese, and sends abroad nearly as much butter, which sells for a higher price than butter from the United States. The United Kingdom imports 350,000,000 pounds of butter, of which not 5% comes from the United States. This country permitted imitation cheese and imitation butter to be exported as the genuine articles. European consumers soon found that they were swindled and refused to buy either cheese or butter from this country. As a result our export trade in those articles fell off to insignificant figures.

Canada would neither permit the manufacture nor export imitation butter or cheese. Hence our loss was Canada's gain. Her exports in cheese and butter increased in proportion as those of the United States declined. This result was not because she could produce better or cheaper butter and cheese, but for the reason that European consumers could be sure of getting the real articles when purchasing cheese and butter that came from Canada.

Congress legislated to some extent on the question when it was too late. Our exports of cheese this year are only about one-half what they were last year. It looks as though more stringent legislation was needed so far as the export trade is concerned.—*Philadelphia Press.*

It will be remembered in this connection, that the present effort of the dairymen and consumers of the United States to have Congress impose a tax of ten cents on all colored oleomargarine, is but another move in the direction of honesty and the imposing of additional burdens on fraud and dishonesty. The filled cheese law was carried through Congress by the efforts of Congressman Cook, of Wisconsin, backed by the earnest work of the National Dairy Union. As the *Press* says, it was too late to prevent the serious destruction to the reputation of American dairy products which had taken place, but it largely stopped its further disastrous work. The effort to impose a ten cent tax on oleomargarine is in line with the same good purpose. Let every farmer, dairyman and consumer hold up the hands of the National Dairy Union in this most righteous crusade against the colossal fraud and counterfeit of the age.

MAKING PURE MILK.

A "Milking Room" at Fairfield.

Mr. Francisco started twenty years ago, with an output of thirty-five quarts per day. There are now about 500 cows in the dairy, with a daily output of 4,000 quarts. To handle properly this army of cows and ocean of milk requires the labor of sixty men, who are organized into squads, each to do its regular work. The men who handle the horses are not permitted to go near the cows; the milkers must change their clothes and wash their hands before milking; the cows are carefully brushed and carded every day; in fact, every possible precaution is taken to insure absolutely clean and pure milk.

I went to the dairy on July 19th, with the Essex Co. (N. J.) Medical Society, to inspect a new contrivance—"the milking room." There were about seventy-five doctors present, all of whom were interested in securing pure and clean milk for their patients. Every good doctor knows what a large proportion of the people he treats, are at the mercy of the milk they drink. The drugs he uses must be pure and of standard strength or he cannot foretell their effect. The milk that feeds the children and invalids, must be free from harmful germs, or it will upset all his skill. The Essex Co. doctors keep an eye on the Fairfield Dairy, and many of their ideas and suggestions have been put into practice by Mr. Francisco.

The latest scheme is a "milking room." This is a light, airy room, built out from the main stable, with three sides open to sun and air. It contains places for twenty-four cows. The milkers stay in this room entirely. The cows are driven in and milked, and then driven back, while another squad take their places. Thus no milking is done where the cows eat and sleep, and the milk does not come near the bedding and manure. The milk is drawn into closed sanitary milk pails, which are wiped with a damp cloth before the milk is strained into the cans. The cans are carried on a steel cable, high in the air, to a distant milk house, where it is quickly cooled on a great Star cooler and at once bottled and packed in ice. From the cow to the cooler, few germs have a chance to get into the milk, and after that the low temperature has a very chilling effect on the few that do enter.—*Rural New-Yorker.*

Poultry Raising as a Profitable Side Issue.

We consider our poultry one of our greatest helps in bringing the profit side of our books upwards, instead of the reverse. However, we do not expect them to take care of themselves and then bring in a profit. We generally keep from 150 to 200 hens, and for that number of hens we have two good, warm, dry, roomy hen houses with large windows in each end so they can be kept well ventilated. These houses are thoroughly cleaned out every week or two. The roosts are taken out each time and painted with liquid lice exterminator to keep down lice and mites, the later being the worst enemy of poultry in this locality. Then lime is scattered plentifully over the floor and side walls and our hens enjoy a clean sleeping place. We have another house we call the setting hen house. This house is about ten by fourteen and without a floor, so we can place the boxes for the setting hen on the ground, thus getting more moisture for the eggs than when the hens sit on a board floor or in a high nest. When Mrs. Biddy gets broody we allow her to set about five days, then we prepare the box for her by first painting the inner sides and bottom with the lice exterminator, then put in enough fresh hay to make a comfortable nest, next put in the eggs and sprinkle them with Persian insect powder. After dark we get the hen and place her on the nest, then leave her alone; having previously provided her with kafir corn, water and a box with ashes and a little sulphur mixed as a dust bath. We attend to putting feed and water in this room about three times a week and the hen does the rest, bringing forth a nice brood of healthy little chicks free from lice. There is no trouble of turning off and feeding and then putting back and shutting up the hen. Anyone who tries the above will never set hens the old way again. We usually set from seven to nine hens in this room at one time. When the little chicks are hatched we give from fifteen to eighteen to one hen and turn part of the hens out to lay again, then we clean all the boxes and the ground and put in a fresh lot of biddies to set. For the hens and little chicks we use good sized dry goods boxes with slatted fronts made of lath. Near these we have a self feeder, as we call it, made of lath, and about five by six feet square and high enough to place on an upright box, fixed on the same plan as the self feeders used for hogs. This is kept full of kafir corn or other fine food for the little fellows and the hens cannot disturb them. We also keep a pan of fresh water convenient for them. We raise from 250 to 300 in this way with less work than many have in raising one hundred. In October we look over our old hens and select the nice, plump breasted ones and those we know to be the youngest to keep over for another year, for we think old hens will set sooner in the spring than pullets and also make better mothers. We look over the pullets and sell all inferior ones. In October the pullets are broken to sleep in the hen house by shutting them together with the hens, in the yard surrounding the house for a week, after that they will go in of their own accord. On stormy days they are kept in this yard also. We keep a plentiful supply of feed before them, giving kafir corn principally. We feed a warm mash every morning and give some tonic once a week to keep them healthy. We keep mostly Rose Comb Brown Leghorns with a few Langshans and other varieties.

Mrs. C. B. E., in *Prairie Farmer.*

On Milking.

It is not a paradox to say that there are several ways of milking cows. The best way is that which obtains the maximum quantity of milk. To this end, therefore, the dairy farmer is bound to regard the operation of milking as one of the greatest importance, and one which involves certain actions, all of them simple, some of which, to the man who does not understand cows, may even appear childish. As an instance, we may mention that the Normandy milkmaid is taught from her childhood always to sing softly to the cows she is milking. The object, of course, is to keep the animal in good humor, to induce her to forget that she is being milked, and—sensitive creature as she is—to prevent her from keeping back her milk. Indeed, the beneficial effect of music on the flow of milk is by many thought so great that we have heard an American dairy farmer seriously say that it would pay the owner of a large herd to employ a band to discourse sweet music during milking time.

Apart, however, from hypothetical considerations, there are others which should be always carefully followed. Remembering the fact that the mammary glands are particularly active during the actual period of milking, it is of importance that the act of milking be continuous, without intermission from the beginning to the end. Gently pressing the cow's flank with his head, the milkman should firmly grasp with his hands teats which are diagonally opposite. They should be grasped sufficiently high to slightly compress the udder. The motion of each hand should then be alternately upwards and downward. The milking should be slow at first, then gradually accelerated, until a quick motion has been attained which should be continued rythmically to the end of the flow of milk.

The importance of milking to dryness cannot be too strongly impressed, when it is remembered that the milk which is last drawn contains the largest proportions of butterfat.

A person who is not gentle to cows should never be allowed to milk them. Nor is their sensitiveness to be forgotten. The milkman who does not walk straight up to a cow in a field, but who makes a detour to reach her, is a man who fully appreciates the timidity of the dairy cow.

The foregoing considerations relate to the quantity of milk to be obtained. As regards the milk actually yielded, the most important factor is that of cleanliness, though it is the one perhaps the least considered. The milker should always wash his hands carefully, as well as the cow's teats, before milking. It is better also to waste the first few jets of milk which issue from the udder, and which may contain some deleterious bacteria, than to run the risk of spoiling the amount kept, by obtaining a slightly larger quantity of milk.—*Dairy World*, England.

GOOD WHEELS
MAKE A GOOD WAGON.
Unless a wagon has good wheels it is useless.
ELECTRIC STEEL WHEELS
are good wheels and they make a wagon last indefinitely. They are made high or low, any width of tire, to fit any skein. They can't get loose, rot or break down. They last always. Catalog free.
Electric Wheel Co., Box 130 Quincy, Ills.

Dark or White Shelled Eggs.

It has long been a pet theory on the part of those who happen to be the breeders and owners of birds producing dark shelled eggs that such eggs are richer and better in every sense than eggs having white shells. A set of experiments has recently been carried out by a thoroughly scientific analytical chemist to test the truth of this theory, and it turns out that if there is any natural difference the advantage rests with white shelled eggs; so away goes one strong reason for keeping Langshan fowls. These fowls lay the deepest tinted eggs of any fowls in existence. If they do lay a richer egg than any other fowl, it must spring from another cause, and that is concentration, as they lay the smallest eggs of all the large breeds of fowls. It is quite conceivable that it is possible that the smaller class of eggs laid by the larger fowls may be richer, but we have long held the opinion that the principal factor in giving the richness and pleasantness of eggs, is the food they eat, and from our own observation the very best flavored eggs are produced by fowls having a free run on heathery hillsides, and no doubt, the richness of the flavor is derived from the large amount of insects procurable. The inference, then, is that if you want richly flavored eggs you must take care that your fowls have a fair supply of sound, sweet flesh, for be it remembered that the bulk of animal food procured in the shape of insects is actually eaten alive, and so are perfectly sweet.

That the flavor of eggs can be sensibly affected by the food they eat is proved by the fact that eggs laid by fowls and ducks that have access to fish, lay eggs having a strongly fishy taste. We have no wish or intention of writing anything to injure the repute of the Langshan fowls or any other laying dark shelled eggs, as we confess to have a liking for dark shelled eggs, and we are yet in doubt as to whether an analysis can seize upon the most valuable property of a fresh egg —viz., its flavor. Whilst we, therefore, are prepared to adopt the accuracy of the chemist's deductions as to the actual feeding values of the different eggs, we are still inclined to the opinion that small, dark-shelled eggs are of richer flavor than the large white shelled ones, but we also believe that food has the most important part to play, and for the reason that the eggs of hens too freely fed on potatoes are liable to be very much lacking in richness of flavor. The plain lesson from these remarks (which remarks are based on facts) is that if you wish to have richly flavored eggs, you must feed rich and varied food, a fair amount of which shall be sweet, animal food.—*Scottish Farmer.*

Feeding the Pig for Pork.

What is a complete food for the pig, and will it pay to feed some wheat even when wheat is pretty high in price? If wheat is fed with corn meal the results are highly satisfactroy. Bran, because of its character of composition, is not a wholly desirable feed for pigs. Middlings may be fed with profit at any time during the hog's life. They are not only rich in protein and ash, but are what may be called a clean, smooth food, being free from the objectionable crude fiber which so prominently distinguishes bran. Barley is an excellent food, and will enable such sections as Northern Dakota and Montana to produce some of the best pork in the world. In these and other sections like them, barley and peas will make pork production profitable, if given the opportunity. Peas, as all understand, are a highly nitrogenous food, and when dry, should always be fed with some other grain.

There are some who do not appreciate the value of clover hay for swine. It is to be regretted that such appreciation is not universal. It is not only valuable because of its high merit as a feed, but because of the bulk that it furnishes. No growing animal should be fed exclusively upon the grains. Swine will eat dry clover hay with a relish, but the better way to feed it is to cut it up, steam it or pour hot water on it, and mix with meal. Pasture, if it is the right kind of pasture, is nearly an essential in profitable swine raising. It should be clover pasture, but if it is not, it must be composed of short and tender grass.

NEW 20th CENTURY

STYLES, CAPACITIES AND PRICES

OF THE LATEST IMPROVED

De Laval "Alpha" Cream Separators

"BABY" OR "DAIRY" SIZES.

SEPTEMBER FIRST marks the introduction of the Improved 20th Century "Baby" or "Dairy sizes and styles of "Alpha" De Laval Cream Separators. These improvements denote another advance in centrifugal cream separator construction and efficiency. Great as has been the universally conceded superiority of the De Laval machines heretofore, the standard is now raised still higher. As near practical perfection as have been the De Laval separators the past year, the latest improvements make them still better, until it is difficult to-day to perceive the possibilities of further improvement.

There has been a two-fold purpose upon the part of the De Laval makers in this respect. In the first place, they have had their skilled experts at work for three years to devise every conceivable means of bettering their machines, with which to fittingly celebrate the trade opening of the new century. Following precedent in the development of the De Laval machines no expense has been spared to this end. Nor has cost of production been considered in the determination of the makers to give the 20th Century purchasers of a De Laval separator as nearly perfect a machine for the purpose as twenty years of experience could devise and the finest shops of the kind in the world produce. That this result has been achieved will be instantly apparent to any one familiar with cream separators on *seeing* the new machines. And when it comes to *operating* one of them the previous user of separators will readily find that the 20th Century machines are in a class by themselves in efficiency and completeness, while the *longer* he uses one of them the greater will be his appreciation of its superior practicability and durability.

In the second place, while the sale of the De Laval machines has always been five times that of all others combined, it has been a problem with the De Laval makers for several years how best to so convincingly demonstrate the all-around greater merit of the "Alpha" machines to every intending buyer as to make their use as universal as the overwhelming superiority of the "Alpha" disc construction justifies it should be and must ultimately make it and thus lessen the temptation of the inexperienced buyer to take chances with one of the inferior and supposedly "cheaper" separators which the expiration of the original patents on the "hollow bowl" type of separator has led several former manufacturers of gravity creamers to take up and attempt to find a market for on their own account. This the De Laval makers confidently believe they have accomplished in the machines now launched upon the market. These machines are now advanced so far beyond everything else for the clarification of milk and the separation of cream from milk that they are simply unapproachable in principle except through infringement of the "Alpha" disc processes, and in mechanical construction and practical cheapness except through manufacture on as large a scale and with equal experience,—all of which, moreover, must be readily and convincingly apparent to any one with even the most casual consideration.

While furthermore, the American use of dairy cream separators is as yet in its infancy. Where there are five machines used in a locality to-day there will within five years be fully fifty. Within five years the home and farm use of centrifugal separators will be as universal as is their creamery or factory use to-day. Every one creaming milk for any purpose or in any quantity must use the centrifugal method when once really cognizant of its advantages. Within another five years every quart of milk marketed for human consumption will be first centrifugally clarified and purified by passing it through an "Alpha" disc machine, without utilizing the separation features. This is the assured future of the centrifugal cream separator, but preliminarily necessary to such broader sale are thoroughly pract cal machines for inexperienced home and farm use,—machines large in capacity and *easy of hand operation,* simple, durable, complete in finish and attachments, thoroughly efficient, and at same time reasonably low in price in proportion to resulting benefits. Such separators the De Laval makers present to the public in the new 20th Century machines—machines for everybody, that nobody can criticize and nobody ask for anything better or cheaper.

Lice on Poultry and How to Destroy Them.

It is mainly young birds that are affected by parasites; the adults, though greatly inconvenienced, feel the presence of the unbidden guests far less. Parasites are both internal and external; the external ones may be permanent or partial parasites; they may remain on their host or only go to their host at feeding time. Many parasites develop by means of a very complicated series of changes, which have to be passed in either two different hosts or in different parts of the same host. In the former case the knowledge of the parasite's life history may very materially help us to check its increase or to even stamp it out. With one exception in poultry, namely, the tapeworms, no such complicated life history exists, and with regard to these tapeworms we know little or nothing. The parasitic diseases of poultry may be grouped under two heads, namely:

1. Animal parasites.
2. Plant Parasites.

The former are far and away the most important, nevertheless fowls suffer very severely from one vegetable parasitic disease called "favus."

Of poultry parasites I regard the bird lice, scientifically called Mallophaga, as the most prejudicial, as they cause the greatest loss, both directly and indirectly, to poultry keepers. These lice, of which eight species are found on the fowl, four on the duck, five on the goose, and three on the turkey, are more or less permanently parasitic, but they may, in the case of certain species, leave their host and pass part of their time in the nests, but generally speaking they only leave their host to go to another individual. There is a very general idea that these lice pierce the skin of the bird and suck out the blood. No such thing.

These bird lice have a true biting mouth, by means of which they gnaw away at the so-called epidermal products of the skin, namely, the feathers, the base of the feathers, the scales, and the skin itself. Now, we must remember that the skin is very sensitive, and the result of this gnawing is to set up violent itching. This irritation, produced by bird lice, causes very considerable loss, in two distinct ways. Brood hens are very frequently covered by two species of these insect pests, which attach themselves very closely to their chest; and by a third species, which can be found wandering from bird to nest occasionally. This latter creature is the one that covers the hands when plucking a fowl.

These lice congregate under the wings and around the rump in particular, but the latter wanders all over the body. They set up constant irritation, an inflamed condition of the skin results, and thus the pruritus increases in extent and violence from day to day. The result is that the birds become restless, and I believe that a great percentage of failures in hatching are due to this cause. Secondly, I am convinced from experiment and from the numerous reports sent to me by fanciers and others, that certain lice prove very prejudicial to chicks. We frequently find a "tick-like" species attached to the head and necks of chicks and poults. These lice cause severe irritation to the tender skin, worry and annoy the chicks, stop them feeding, and although they do not actually suck the blood, they scrape so hard at the skin as to cause such serious pathological disturbances as weaken the system. The result is that the growth of the chick is hindered, and the individual never makes up for this check at the critical period of its development. Such few observations as I have made by comparing lousy and clean chicks, at the end of the year, fully bear out this point that many pratical men have noticed. Lice are also partly the cause of "feather eating," for a bird will often peck at the nits and lice on another bird and pull feathers out in so doing.

All observers abroad, and the few who have paid attention to this subject in England, are agreed that these wingless insects breed all the year round, but especially in the spring. The eggs are laid by the female on the feathers of the host, especially amongst the "down feathers," to which they are attached by numerous fine threads at their base. In from six to ten days they come forth as young lice, very like the adult, only paler in color, and at once commence to irritate the host. They gradually grow by a series of moults into the adult form. Some few may breed in the nest, but speaking generally, reproduction and development take place on the bird.

There are three distinct ways in which they are distributed from bird to bird—namely, by the cock, by detached specimens that may be found in the nest, and by certain two-winged flies that are parasitic on poultry. Dr. Sharp exhibited at the Entomological Society in 1890 one of these two-winged insects with several of these bird lice upon it. The pests are undoubtedly spread by the cock, and also to some extent from bird to bird, via the nests. The part played by the two-winged flies is not of much account although of interest. One, I fancy, connot be too careful in regard to a new cock in seeing that it is free from such and other pests, for I believe this to be one of the most fruitful sources of infection in such-like diseases. A thorough examination should be made of the bird before he is allowed to run with the hens, not wasted time, for it may possibly save much future inconvenience. Hens, of course, also carry lice.

Medical science teaches us that weakness and a debiliated constitution are often the precursors of disease. Just as with man so with our birds. Lice weaken the constitution and cause a general unhealthy condition, the result is that the patients are more liable to contract such fatal or troublesome maladies often appearing in epizootic form, as diphtheritic roup, gapes and chicken cholera. In every case of diphtheritic roup I have examined, lice swarmed over the bird, and the first stage of treating the patients is to rid them of these insect pests. Lice also prevents sick birds from recovering when out of health.

Lice can easily be checked, and I feel sure it is to every poultry breeder's advantage, whether he be a fancier or farmer, to take steps to do so. Dust baths should always be allowed, having some insectifuge mixed with the dust. Half dust and half gypsum, steeped in paraffin, is a good mixture for these natural baths of gallinaceous birds. Broody hens should always be treated previous to being placed on the eggs. A small quantity of mercurial ointment or white percipitate should be rubbed into the base of the feathers around the anus and under the wings, and other places where lice congregate. The nest box should be well disinfected, and lime placed on the floor, and pyrethrum sprinkled over the nesting material.

Young chicks, as soon as any signs of lice are seen, should all be dressed up the neck and head with this ointment—the smallest quantity only, as it is poisonous. Every fresh bird should be examined and cleaned before being allowed to run with the rest. Roosts must be kept scrupulously clean, especially the nests and perches. It is important that the houses should be well constructed, for when badly built the cracks and joints harbor countless pests, which may not be reached by any insecticide used. The fowl's worst enemy and greatest source of annoyance may then be checked, or even obliterated entirely.—F. V. THEOBALD, in *Farmer's Gazette*, Ireland.

The Schmidt Treatment for Milk Fever.

An account is given in the *Veterinary Record*, by Mr. Rowland G. Saunders, M. R. C. V. S., of the Colonial College, of his treatment of a case of milk fever under the Schmidt method. The following is Mr. Saunder's description of the case: "The subject was a fourteen-year-old Short-horn cow in good condition, and having the reputation of a good milker. She calved on Friday morning, June 16th, and at four p. m. on Saturday she was found showing partial paralysis of the hind limbs. She could only just walk, the feet being brought forward with great difficulty, while her quarters swayed to and fro in the characteristic manner. The eyes were staring and the pupils somewhat dilated. She kept much in this condition throughout the rest of the day, except that the paralysis became rather more pronounced. She went down and got up again with difficulty; and we left her standing the last thing that night. As we so often have cases of post-partum paralysis amongst our cows here, I did not feel convinced that this was going to develop into milk fever; so I delayed injecting the potassium iodide, and the last thing gave a drench containing a a pound of sulphate of magnesium and six drachms of aloes, as she had passed no fæces for some time previously. I was called at 5 a. m. Sunday and on going to the dairy I found her down, almost unconscious, with her head turned to the right side. Her ears and limbs were cold, respirations were slightly accelerated (32), the pulse was small and frequent (76), and the temperature 90.2, which latter symptom I regarded as a very unfavorable sign.

We immediately milked her dry and (after washing the udder with soap and warm water followed by a two per cent lysol solution) I proceeded to inject two drachms of potassium iodide dissolved in a pint of boiled water at the body temperature, a quarter into each teat. It was injected with an Arnold milk fever syringe, the air was admitted at the same time. The udder was afterwards hand rubbed, to equally distribute the solution throughout the gland. I did not consider it safe to drench her. We kept her as much as possible on her sternum or chest during the day by means of sacks of straw. A quantity of hard fæces was removed, salt enemata were given at intervals and the urine removed, there being a large amount on first passing the catheter. The pulse beats remained the same in frequency, although they became weaker.

By three p. m. I was disappointed to find that the temperature had fallen still further to 88.3. During my absence and against my strict injunctions, the attendant attempted to drench her, and succeeded in getting some gruel 'the wrong way.' Small quantities of milk were stripped from the udder at intervals. In the evening she was lying in the same position with her head to the right side, except that they had turned her over twice. A thin discharge was flowing from her nostrils. The rectum contained fæces softer in consistence. At times there were very fetid eructations of gas. At ten p. m. she seemed rather worse than better, and showed no sign of returning consciousness. I inject-

W. R. THOMAS, Bellmore, Ind., Breeder of Jersey Cattle Stock for sale. Write for prices. Correspondence solicited.

Dry Weather here earlier in the season so reduced our feed that we offer, to reduce numbers, some of our **BEST COWS and HEIFERS.** Some are fresh and others will calve in the fall. Our sale list No. 5 gives short pedigrees and includes recently dropped bull calves, also a yearling fit for light use. It will pay anyone wanting **Jerseys** to send for this list. A postal will bring it and a booklet of the herd, if this paper is mentioned. **WINTERGREEN HILL FARM CO., Scottsville, N. Y.**

FOR SALE! **DOUBLE GRANDSON OF** **Exile of St. Lambert 13657,** **78 Tested Daughters**—more than any other bull, "Living or Dead." Solid lemon fawn color, one year old. A handsome individual, and **will be sold CHEAP.** **P. J. COGSWELL, Rochester, N. Y.**

Biltmore Farms' JERSEYS. This is a working herd of 250 of the best native and imported breeding, selected for work at the pail, constitution and individuality. All Tubercu lin Tested. Above the fever line, so we can ship anywhere. **SOME CHOICELY BRED** **Bull Calves** out of great cows and by the best sires, for sale at Dairymen's Prices. Also large **English Berkshires,** imported and native bred. Apply to **GEO. F. WESTON, Supt., Biltmore, N. C.**

MILLER & SIBLEYS JERSEYS. Ida's Rioter of St. L. leads all other bulls in average for 29 tested daughters, viz.: over 20 lbs. of butter apiece in a week. All full weekly tests, by eight different owners. He weighed 1,760 lbs. His dam's record, 455½ lbs. milk, 30 lbs. 2¾ oz. butter (official test) in 7 days. **FOR SALE**—Grandsons and granddaughters of Ida's Rioter of St. L.; also cows in calf to his sons. **224** First Prizes and Sweepstakes at 22 State Fairs or great Expositions. **224** Big cows, Sound cows, Heavy Milkers and Great Butter Makers. Our Adelaide of St. Lambert gave 82¾ lbs. milk in one day, 2005¼ lbs. in one month, the world's Jersey record. Many other championship records. No catalogue. Special literature sent if this paper is mentioned. No animal sold for less than $100. Lowest price for quality. Every animal tuberculin tested before sale, if desired. Also for sale, Children's Ponies and Imported Shropshire Sheep. **Franklin, Venango Co., Pa.**

The Lone Tree Jerseys THE largest collection of **high testing cattle** in the West, including **home-bred** and **Island cows. Show** and **Breeding Stock** always in supply. **Especial attention** given to furnishing **foundation stock for pedigreed herds.** A superb lot of young bulls and heifers now in special offer, including some sure prize winners. **Introduce Fresh Island Blood Into Your Herd.** SIRES IN SERVICE:—The prize winning **IDA'S RIOTER OF ST. LAMBERT 10th,** the champion **CATONO KHEDIVE,** the champion **CZAR COOMASSIE,** and **IMP. GOLDEN BAR,** inbred through his sire, Aristocrat, and his dam, Imp. Sandgate, to Golden Lad, the greatest bull on the Island of Jersey. Write for what you want. Visitors always welcome. **JOHN E. ROBBINS, Greensburg, Ind.**

Butter Bred Bull Calf, 10 MOS. OLD, a Little White. Very handsome . . . Send For Pedigree. **$50.** **J. P. BRADBURY Pomeroy, Ohio.**

ed another two drachms of the salt into the udder and left her well propped up with straw sacks for the night.

On Monday, ten a. m., she was still down, but was fast regaining consciousness. Tears were flowing from her eyes, and a rather thick discharge from the nostrils. Pulse, 68, rather stronger; respirations, 28, and temperature 99.4. At midday she was still improving, and on making an attempt almost got up. Throughout the day she had small doses of rectified spirit and spirit of ammonia in gruel every two hours. Small quantities of milk were taken from her at intervals. At nine p. m. she regained her feet, but looked very dull and sleepy. She was disinclined to move and when made to do so staggered a good deal. She ate a bran mash and drank a pail of water. On Tuesday she was still improving, although still showing much lassitude. At mid-day three pints of milk were stripped from her, and shortly after the calf was put back with her again; but she took little notice of it. On Wednesday she was quite convalescent, and was feeding well and giving almost her full quantity of milk. There was no sign of any abnormality of any part of the udder.

I am fully aware that it is extremely difficult to say that a particular cow would have died without a particular mode of treatment, as so many presenting very unfavorable symptoms from the first, make good recoveries with or without treatment, while, on the other hand, seemingly benign cases often disappoint us by terminating fatally. With milk fever we are unfortunate in the fact that up to the present we have failed to discover any symptoms which are of much use in arriving at a prognosis. I have brief notes of some eighteen cases that were treated with chloral, and with them the only symptom that I have found of any use whatever in forming a prognosis has been the temperature. Where a cow's temperature has fallen below 100 F. within a few hours after showing the first symptoms, I have invariably seen such a case terminate fatally. On the other hand, the opposite does not hold good, as a cow will in some cases die although during the whole of her illness the temperature has never dropped below 100°.

Of course, it is quite possible that a wider experience may disprove this, but be it as it may be, until I have proof to the contrary, I feel justified in attributing the recovery of a cow with a temperature below 100° to whatever treatment was adopted, and not to nature unaided. The above is the first case with such a low temperature that I have seen recover, and therefore I shall certainly use Schmidt's treatment for these cases in future, not neglecting other important points, as keeping the patient propped up on her sternum, taking the urine away, etc. I venture to think that when mammitis occurs as the result of the injection it is due more to uncleanliness of the syringe, or of the udder, than to the irritant effect of the potassium iodide.—*Agricultural Gazette*, Ireland.

The Thoroughbred the Farmer's Fowl.

It is with great pleasure that I hear every day of the increasing demand for thoroughbreds on our great poultry farms. I really believe that even our small farmers are waking up to the fact that a dunghill fowl is a poor investment. It has been a long row to hoe, but we may congratulate ourselves that the thoroughbred is winning its way, even with the most prejudiced. Of course this is greatly due to the improvement in our different money-making breeds. Such grand breeds as our Plymouth Rocks, Wyandottes and Brahmas are attractive enough to fascinate even the most skeptical. It is useless to announce to the expert breeders of these varieties what their good qualities are; on the contrary, we depend on these breeders to tell us of them. It is from such breeders that we learn of improvements in condition and laying qualities.

We hardly can expect the average farmer to try experiments with fowls. He has plenty of other work to do, and it is customary to leave the care of the hens to the good wife. It costs no more to feed a first-class fowl than it does to feed a dunghill, and the former will lay many more eggs than the latter. Does such a statement appeal to a farmer? Yes, it may, but he does not believe it to be a fact. To him a hen is a hen, and she is supposed to lay eggs. Occasionally he discovers that one hen is a better layer than another; yet I doubt very much whether he ever stops to consider why. The hardest task is to convince our farmer friend that a hen costing $1.50 can possibly be any better than one costing fifty cents. This latter is the price usually considered high enough for any hen.

It is through the laying quality alone of a thoroughbred that we must try to convince the farmer that it is better than a dunghill. Eggs, and plenty of them, appeal to him. He can produce a chicken and a plump rooster quite good enough for the market stall, from his dunghills, and at but little cost for feed and care. I doubt very much whether it would pay the average farmer to raise what are known as first-class broilers. It would take much of his time, and in order to put broilers on the market early enough to catch the highest price, he would be obliged to use incubators and set his eggs as early as December and January. To obtain fertile eggs so early means skillful and scientific breeding, which would take him out of the ordinary rut of the farmer and make him an expert. Setting eggs under a hen is more to his liking, and besides, the hens move along in their natural way and set when they become broody. His chicks mature to broiler age about August 1st, and this is early enough for him to realize a little profit.

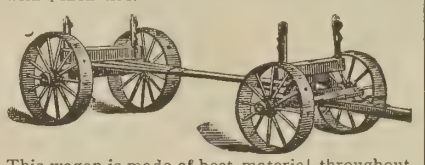
The first step, therefore, towards inducing him to adopt thoroughbreds is through the increase in the egg-yield. If he can see that for no more expense in feed and care he can obtain more eggs from each hen, it is a convincing argument that they are better. Once having bought or acquired by trade, or in any other way having obtained some thoroughbreds, he must remember to keep them separated from the rest of his flock. The safest way to do this, and to be free from all anxiety, as to contamination from his common fowls, is to get rid of the latter entirely and keep nothing but thoroughbreds —so many mistakes have been made by farmers buying first-class thoroughbred hens and then letting them run at large with the rest of the flock.

This is a fatal error. It is the reverse of what is intended, for it improves slightly his common fowls and ruins his thoroughbreds in one season. Thoroughbreds must be kept pure. If a new male is desired for next year, he must of course be of the same breed and variety as the original stock. Barred Plymouth Rocks must be kept always Barred and not crossed by White or Buff, thinking that because they are all Plymouth Rocks it will do as well. This will probably sound absurd to breeders of these varieties, but it has been done frequently, and the farmers were perfectly ignorant that they had begun crossing in color. Of course it does not materially decrease the value of the breed as far as the flock is concerned, and it may not decrease the egg yield, as all Plymouth Rocks are good layers, but it may degenerate into careless crossing, which will soon reduce the thoroughbred to a dunghill.

Thoroughbreds, when from good laying strains, can be kept good layers only by careful attention. The eggs from the best layers, for example, those that lay first and continue the longest, should be given the preference for setting over those of others that lay later and stop earlier. Early and good layers will reproduce the same quality in their pullets. A strain kept in this manner for years, with the care necessary to keep them in good condition, will develop a prolific laying strain which will become of great value as money makers. Again, there is little value in a layer after her hen year. She will lay her best in pullet year and a little less in hen year; then she should be disposed of. If no other way presents itself, she will always bring a good price in the market as a dressed or live fowl.

It is in this very point of age that farmers make great mistakes. If a hen is considered a good layer, she usually becomes a pet and is kept on indefinitely, until she dies of old age or disease. Little do they stop to think that she is lay ng fewer and fewer eggs. The feed that she requires would keep a first-class layer, which would be a source of considerable income. It is in these small points of economy that money can be made. The thoroughbred is the farmers' fowl She is a producer and a money-maker, and she will stand good care and abuse equally well. She is worthy of the former and often gets the latter, but her blood and breeding stand her in good stead, and stamp her, through any and all conditions, the best of our domestic fowls.—*Country Gentleman.*

Skim Milk as a Food for Milch Cows.



Mr. J. Lindstroem, a Swedish farmer, has conducted experiments with a view of utilizing skim milk as a food for milch cows. He recently gave an interesting account of his experiments and of the method of proceedure followed, in making the "skim milk food," the main features of which are given below. The milk is first pasteurized, or simply boiled, in order to kill all bacteria which it may contain. It is then cooled to 80°, and rennet is added. When the milk has coagulated, as much chaffed straw as there is curd is added. This mass is mixed in a tank or vat, and left for two or three hours. The whey not absorbed by the straw is run off, and the whole is left for forty-eight hours, when it will be fermented and ready to feed. It is stated that enough of this food may be fed to correspond to four kilos (8.8 lbs.) of whole milk per head per day, and this will replace about four and one-half pounds of ordinary grain food. The method appears to be simple and easily worked. No doubt, other coarse foods, also ground oats, etc., can be incorporated with the curd in the manner described.—*The Dairy*, England.

Food Value of Koumiss.

According to one authority; one and one-half gallon of mare's koumiss contains as much nutriment as a strong adult requires during one day. Many persons prefer skim milk koumiss—or koumys, as it is sometimes spelled. During the warm weather, when every one is inclined to drink freely, the use of koumiss is a wholesome and nutritious addition to our summer drinks.

A Low Wagon at a Low Price.

In order to introduce their Low Metal Wheels with Wide Tires, the Empire Manufacturing Company, Quincy, Ill., have placed upon the market a Farmer's Handy Wagon, that is only 25 inches high, fitted with 24 and 30 inch wheels with 4 inch tire.

This wagon is made of best material throughout, and really costs but a trifle more than a set of new wheels and fully guaranteed for one year. Catalogue giving a full description will be mailed upon application by the Empire Manufacturing Company, Quincy, Ill., who also will furnish metal wheels at low prices made any size and width of tire to fit any axle.

OAK GROVE HERD H-F. Cattle.
Cows, Heifers and Bull Calves For Sale.
C. H. Stevens, Jefferson, Wis.

High Test I offer the grand young bull Prince Mercedes DeKol, whose 4 nearest tested relatives have an average equivalent record of 24½ lbs. and 4.14% fat, and have won 1st, 2d, and two 3d prizes in H.-F. Offic'l Prize Contests. Others extra good. MALCOLM H. GARDNER, Darien, Wis.

104 Holsteins For Sale.
Young Bulls and Heifers by the richly bred **Royal Paul.** Prices right for quality. Show animals, all ages, bred for butter makers.
DELLHURST FARM, Mentor, Ohio.

HOLSTEIN-FRIESIAN CATTLE
Owned by **JONES & RANDALL, Hustisford, Wis.** 100 head to select from. From families rich in butter fat. Herd now headed by Barron Paulina De Kol. Stock for sale. Prices reasonable.

HOME FARM HERD.
Headed by Jewel of Home Farm, Sweepstakes Holstein-Friesian Bull Trans-Mississippi Exposition Omaha, Neb. Seventy-five head to select from. W. B. BARNEY & CO., Hampton, Iowa.

MEADOW LAWN HERD Holstein-Friesians.
Herd headed by **Sir Brookside De Kol.** Choice young stock for sale. Come and see them. C. W. HARRISON, Ringwood, McHenry Co., Ill.

Holstein-Friesians
MECHTHILDE BULLS FOR SALE.
Address M. W. BARDEN, Portage, Wis.

McGEOCH FARM Holstein-Friesians.
Herd headed by Gem Pietertje Hengerveld Paul De Kol and Johanna Paul Colantha. A few young bulls, 3 to 7 months old for sale at bargain prices. H. B. DAGGET, Mgr., Lake Mills, Wis

NATSEY
The 5th highest butter cow in Holstein history, is owned, with three daughters and her son, at Valley Mead Farm. Natsey's butter record for 1889 is 30 lbs. 9 ozs. in seven days. In 1890, 34 lbs. 9 ozs. in seven days, which is the largest record of the breed in the advance registry. Her milk record is 85¼ lbs. in one day, 19,491½ lbs. in 11 mos. 28 days. HOARD'S DAIRYMAN says: "Look the cow over from head to tail and from horn to hoof, and it would be difficult to fault her anywhere." FOR SALE—A few bull calves, grandsons of Natsey. VALLEY MEAD FARM, Monticello, Wis.

Markham Manor Farms. Simonsville P. O., Andover, Vt.
Holstein-Friesian cattle bred from the most fashionable butter families, individually large producers, and of the most approved show form. The herd contains seven daughters of Sir Netherland Soldene Clothilde, No. 18390, H. F. H. B., the most remarkable show bull of recent years. Also large English Berkshire Swine from noted prize winning and imported stock. Write for description and prices to J. A. THORNTON, Mgr., Simonsville, Vt.

130 Holsteins. First prize herd at Trans-Mississippi Exposition at Omaha. 1st and 2nd on aged cows and 1st. on two-year-old heifer in the seven day butter test, open to all breeds at same Exposition. Three cows in this herd have produced the most butter in seven days of any cows ever officially tested. A score of others nearly as good. Our richest bred bull calves are taken young. Sons of De Kol 2d and Netherland Hengerveld head the herd. Animals of both sex and any age for sale. Write stating just what you want. HENRY STEVENS & SONS, Lacona, Oswego Co., N. Y.

Milk Cans.

We make all grades and patterns. Our Catalogue shows them. Write for it.
BUHL STAMPING CO., Detroit, Mich.

HOLSTEIN CATTLE! The Choicest Milk and Butter Breed in the World. Write to Wis. Live Stock Ass'n, Appleton, Wis., U.S.A.

SHADY NOOK HERD Holstein-Friesians Choice Chester-White
Pigs 2 to 3 months old, both sexes, for sale.
W. R. GATES, Ripley, Jefferson Co., Wis.

Registered Holstein-Friesian Cattle. Best families of the breed. Aaggies, Waynes, De Kols, Netherlands, Pauline Pauls, Pietertjes. WM. O. JACKSON & SONS, South Bend, Ind.

GUERNSEYS FOR SALE. The increase of my herd is a few young things of both sexes, from one to eighteen months old. Prices corresponding to age and quality. F. W. TRATT, Whitewater, Wis.

GUERNSEY CATTLE
SHETLAND PONIES.
Old Homestead Herd,
Of PERRY, OHIO,
Was Champion at O., Ill., and Ind. State Fairs, 1898, winning against well-known O., Pa., and N. J. Guernsey show herds. Over twice as much prize money as all competitors combined at above fairs. No better collection in America. Breeding Stock For Sale. Inspection invited. Will make a representative exhibit at the Ohio, Wis., Ind and Ill. State Fairs this fall. L. V. AXTELL, Perry, Lake Co., O.

REGISTERED
GUERNSEY BULLS
We offer several well-bred young Guernsey Bulls, dropped in April and May, '99, at **$25.00 Each,** registered and transferred. They are handsome and well grown and grandsons of Gold Bound No. 2726, bred by Mr. Levi P. Morton and sired by Imported Midas 2003. Dam, Imported Lady Antornelle 2d, 3680. M. B. ROWE & CO., Fredericksburg, Va.

Riverside Guernseys,
CHAMPION Herd
AT NEW YORK STATE FAIR,
1898, in competition with the leading herds of the country, won eight firsts and sweepstakes. Young stock by **COMUS,** sire of most of the winners, for sale. Thoroughbred Poultry—the best egg-producing and general purpose varieties—Leghorns, Wyandotts, Buff Ply. Rocks, Houdans. Send for circular. Stock for sale. J. FORSYTH, Riverside Farm, Owego, Tioga Co., N. Y.

ROSENDALE
GUERNSEYS
Our herd has won first prize at the Wisconsin State Fair every year since 1894, and also won first at Minnesota State Fair and at the Trans-Mississippi Exposition in 1898. We keep only 400-lb. cows. Tuberculin tested.
GEO. C. HILL & SON, Rosendale, Wis.

"Florham" Guernseys.
First Prize Herd wherever shown, viz: New York State Fair, 1895 and 1897; Bay State Fair, 1895; Inter-State Fair, Trenton, N. J., 1895 and 1897; Madison Square Garden, 1895; New Jersey State Fair, 1897. J. L. HOPE, Farm Supt., Madison, N. J.

GUERNSEYS!

Pure Bred **Tamworth Pigs,** Bacon curers choice. Pure Bred **Ayrshire Cattle,** largest imported herd in America. Stock all ages for sale, R. G. STEACY. Box 720 Brockville Ont., Canada.

PIGS Eligible to REGISTRY, and First Class Stock, at Reduced Prices. **Chester White, Berkshire, Poland-China and J. Reds. Thoroughbred and Grade Guernseys. Also Poultry. W. B. HARVEY, West Grove, Pa.**

Alfalfa.—Its Cutting Time.—Its Feeding Value.

(Press Bulletin.)

For the past five years the Utah Experiment Station has been carrying on a line of investigation to determine at just what time in its growth alfalfa should be cut for best results, composition, annual yield per acre, and feeding value, all being taken into account. In connection with this work the feeding value of such well known roughage crops as timothy hay, corn fodder and red clover have been compared with that of alfalfa.

For this experiment a field of alfalfa was divided into three equal pieces; one being regularly cut when the first blooms appeared, the second when in full bloom, and the third when half the blossoms had fallen, these being denominated early, medium and late cuttings, respectively. Incidentally there was made a comparison of the first, second and third crops.

The details of this investigation are reported in Bulletin No. 61 of the Utah Station, a copy of which may be obtained by addressing the Director at Logan. Below are given the more important facts, together with the conclusions that may be legitimately drawn from the results:

1. The largest annual yield of hay per acre is obtained by the method of early cutting and the lowest by the late, the average result standing as follows: Early cutting, 100; medium, 92; and late, 85.

2. The early cut alfalfa contains the highest per cent of protein and fat, the most valuable food constituents, and the lowest per cent of crude fiber, the most indigestible portion. The former decrease constantly, while the latter increases rapidly from early bloom to the full maturity of the plant.

3. The proportionate amount of leaves to stems is greater at early bloom than at any subsequent time, and both leaves and stems contain a greater per cent of protein and a a less per cent of crude fiber at this time than at any later period in the growth of the plant. The relative proportion of leaves to stems in the different cuttings is as follows: Early, 42 to 58; medium, 40 to 60; late, 33 to 67.

4. Alfalfa leaves as compared with stems are very much richer in protein, fat and nitrogen-free extract, and they contain a much smaller proportion of crude fiber. The per cent of the protein and fat grows constantly less and that of the crude fiber greater from the time of early bloom to maturity. The average composition of all cuttings and crops shows the leaves to contain 150 per cent more protein than the stems, 300 per cent more fat, 35 per cent more nitrogen-free extract, and 256 per cent less crude fiber.

5. The more important nutrients, protein and fat, have the highest per cent of digestibility in the early cuttings, and it grows less and less with the age of the plant.

6. In the feeding tests, the highest gains were made from the early cuttings and the lowest from the late, the results standing proportionately as follows: Early cutting, 100; medium, 85; and late, 75.

7. The variation in the amount of the different cuttings eaten per day was very slight, being the highest for the early cutting and the lowest for the late, but the quantity of dry matter and also of digestible matter required for a pound of gain was decidedly lowest for the early cutting and highest for the late, the relative amounts of dry matter standing as follows: Early cutting, 100; medium 131; and late, 166.

8. The annual beef product per acre was largest from the early cuttings, not only in the general average, but in each separate season's test, and that from the late cuttings was smallest, the proportional products standing as follows: Early cutting, 100; medium, 79½; and late, 69½.

9. Taking all points of comparison into consideration, both separately and collectively, including everything that pertains to the largest yield and highest feeding value, the tests favor cutting alfalfa for cattle feeding when the first blooms appear.

CROP COMPARISON.

10. The first crop gave the largest yield in each of the five tests, and in fourteen out of the fifteen cuttings, while the third crop gave the lowest for every test, and in every cutting but one. The average acre yields for the five years, including all cuttings, stand in the following relation: First crop, 100; second, 78; third, 39. For the early cuttings alone, first crop, 100; second, 83; third, 66.

11. In the average composition of all cuttings for three years, the nutrients of the three crops vary but little. The second has slightly the highest per cent of protein and fiber; and the third the most fat and nitrogen free extract.

12. The third crop has the largest proportion of leaves to stems; but the per cent of protein in the leaves is highest in the second crop, and the next highest in the first. The leaves of the first crop contain the most fat, and of the second the least.

13. The third crop produced a higher average rate of gain in the feeding tests than the first or second and also higher than any of the separate cuttings. The amount eaten daily was also highest of all, but the dry matter and digestible matter for a pound of gain were the lowest. In a pound per pound comparison the gains stand as follows: First crop, 100; second, 81; third, 126; dry matter for a pound of gain, first crop, 100; second, 115; and third, 69.

14. The beef product per acre, taking the average result of all cuttings for the five years, was very much the highest for the first crop and decidedly the lowest for the third, standing as follows: First crop, 100; second, 61; and third, 45; But taking the early cuttings alone they stand, first crop, 100; second, 80; and third, 69.

15. Pound per pound, taken as a whole, the results show the highest feeding value for the third crop and the lowest for the second.

16. The average annual beef product from early cut alfalfa was 705.61 pounds per acre; it required 9,575 pounds of timothy to produce an equal weight; 11,967 pounds of red clover, and 10,083 pounds of shredded corn fodder.—*Utah Experiment Station.*

Crimson Clover Seed.

The use of crimson clover (*Trifolium incarnatum*) has increased to such an extent that it is now a standard crop in many parts of the Southern and Middle States. It is distinguished by its long head of brilliant scarlet blossoms and by the great depth to which its roots make their way. Wherever the winters are not too severe it thrives and is a valuable plant for soiling or for hay. It is a winter annual, the seed being sown any time from the middle of July to late fall in the Southern States. It grows throughout the milder weather in winter and quickly makes a dense cover to the ground in spring. This can be pastured, cut for hay, or turned under for green manure, or all three, depending upon conditions.

THE SEED.

The seed of crimson clover is larger than that of red or mammoth clover and is almost perfectly oval in shape. The fresh seed is of a bright, reddish yellow color and has a high polish. As the seed becomes older the color changes to a reddish brown, and eventually the polish is lost and the seed has a dull, dark reddish brown color. Such seed should never be purchased, as it is too old to grow well.

In general the seed of crimson clover is less liable to contain many weed seeds than the seed of other clovers. It is harvested before most of the weeds have matured their seed, and being planted in late summer or fall it tends to choke out what weeds may come up with the young plants. In some cases, however, it contains the seeds of serious weeds and farmers should be on their guard when purchasing. In a number of tests made at this laboratory the seeds of fifty weeds were found to be more or less fre-

frequently present. Most of these occurred but seldom and then only a few seeds in a sample, but sorrel, yellow trefoil and mustard were found in seventy-two per cent of the samples. In the worst samples there were from 3,000 to 6,300 weed seeds per pound, while in one case there were 38,958 seeds of yellow trefoil per pound. The seeds of a species of geranium are not infrequently present. These are of about the size and shape of crimson clover seeds, but lack polish and are marked with fine pits, which are at once evident when the seed is examined with a low-power hand lens.

The most serious adulteration of crimson clover seed is that of Egyptian clover (*Trifolium Alexandrinum*). It is stated that this is not uncommon in European seed, but so far we have not observed it in American samples. The seeds of Egyptian clover are of the same size and color, but the form tends more to egg shape. There are deeper lines on the edge where the rootlet can be seen outlined on the seed. In crimson clover this edge is about as smooth as the back, but in Egyptian clover there is a marked depression on each side of the rootlet.

The worst weed that can possibly get into a clover field is dodder. The seeds being small are seldom found in crimson clover seed, but they may be present in poorly cleaned samples and a lookout should always be kept for them. The seeds of dodder are small and gray and look like minute lumps of clay.

GERMINATION.

While crimson clover seed is comparatively pure, its germination often leaves much to be desired. This seed deteriorates rapidly with age and fresh seed should always be demanded; nor should an assurance of its being fresh be sufficient, but a guarantee of a definite percentage of purity and germination should be demanded from dealers. Seedsmen always disclaim any warranty and as a rule they oppose a guarantee, but there is no reason why clover seed of all kinds should not be guaranteed. The purity can be accurately determined and a simple germination test is all that is needed to determine the vitality of a given sample. Dealers can readily make their own germination tests, as many do now, and there is no excuse for the carelessness of some who sell seeds as they would nails, without the least knowledge of their quality.

Consumers should not only insist on a guarantee, but should test the germination of their seed whether guaranteed or not. This can easily be done at home by anyone. A piece of moist cloth (flannel is best) is laid on a plate, the seeds placed between the folds of the cloth and a second plate inverted over the whole. A certain number of seeds, one hundred or two hundred should be carefully counted out, and the germinating ones removed, and counted as fast as they appear. Germination will begin on the second day, and good seed ought to sprout eighty to ninety per cent in three days.

The importance of the germination test can not be too strongly urged. If preferred, it may be made in the soil. In some respects this is a better test, showing not only how many seeds will produce sprouts, but, also, how many will produce plants. The vigor of the plants can also be noted. The soil test, however, requires more time, and is less convenient than the cloth test, and the latter will show the value of the seed, if note is taken of the number that sprout after the third day, and of those that make weak sprouts. Even though the percentage of germination during a ten-day test, comes up to eighty or ninety per cent, if germination is slow and the sprouts weak, the seed will not give satisfaction. Crimson clover seed germinates rapidly, and in most cases one or two days will be enough to determine whether the seed is fit for use.

Many of the failures with crimson clover are due to the use of old seed, which is sold at a low price. This is discolored, and will show poorer germination, than fresh seed and produce weaker plants. Even fresh seed may, however, be of poor quality. The seed of crimson clover is not easy to harvest. The plants require to be cut when the seed is hard and ripe, but not yet loosened from the plant. If wet weather follows cutting, or if the seed is not properly dried, it becomes discolored, and may begin to sprout. If it is then dried and germination is checked, the vitality of the seed may be seriously injured. It is, therefore, never enough to say that a given sample is fresh, but the consumer should insist upon a guarantee, and upon seed that will test eighty-five to ninety-five per cent. Two-thirds of the samples tested at this laboratory, have germinated more than ninety per cent.

AMOUNT OF SEED TO USE PER ACRE.

The amount of seed per acre varies under different conditions. From twelve to twenty-five pounds has been recommended, but in most cases fifteen to twenty pounds is about the quantity required. The amount needed will, of course, depend upon the quality; a sample that will give ninety per cent of strong sprouts, will go further than one germinating less than fifty per cent. Seed in the husk is sometimes used, and with good results in dry weather. When this is used, more seed is needed, say a bushel per acre. —Circular No. 18 U. S. Dep. Agriculture.

A Special Scholarship in Veterinary Science.

ED. HOARD'S DAIRYMAN:—The McKillip Veterinary College, Chicago, Ill., offers a junior scholarship in that institution, valued at $75.00, to the second year student in the Wisconsin Short Course in Agriculture showing the greatest degree of proficiency in the subject of veterinary science in the Department of Animal Husbandry.

The above generous offer will give the successful young man in the Short Course in agriculture an opportunity to become a veterinary surgeon with comparatively little cost.

In accordance with announcement in Short Course circular and elsewhere, the McKillip College accepts students who have completed the Short Course in Agriculture as juniors, thus enabling them to compete for the degree by attending two sessions. The winner of the scholarship will, therefore, be given the one year's credit on standings from the Short Course and have free tuition for one of the two remaining sessions. R. A. MOORE.

Results of a Sub-earth Duct.

Mr. George Hately, Secretary of the Cheese and Butter Association of Western Ontario, has received the following letter:

In reply to your request for information regarding to the sub-earth ducts which have been recently added to the curing rooms in my district, I submit the following report:

Caistorville—The sub-earth duct is completed and in operation. The duct is eight feet deep and extends 118 feet under ground. It is made of three rows of five-inch tile, two rows of six-inch tile and one row of eight-inch tile, all laid close together with the eight-inch tile in the middle; over the tile there is a covering of rye straw.

In digging the trench for the tile a spring was found near the factory. The water from the spring runs in the bottom of the trench for its entire length, which possibly somewhat increases the moisture in the curing room. The intake pipe is built with galvanized iron, fifteen inches in diameter, and thirty feet high, with cowel on top.

The outlet from the curing room is simply a hole in the ceiling on the opposite side to that at which the duct enters.

On the day on which I visited Caistorville the temperature on the outside in the shade was 85° F. Inside the curing room a strong breeze was coming in from the duct at a temperature of 60° F. The temperature of the curing room did not exceed, during the day, 69° F. The curing room at this factory is very poor. I am of the opinion that with a reasonably good curing room the temperature can easily be held at 65° F. The moisture of the curing room was from 80 to 82. There was no mold on the cheese.

At Woodburn, Caledonia and Canboro, sub-earth ducts have been put in, but were not ready when I visited these factories. On my next visit I will take careful note of the results with the sub-earth ducts and report to you thereon. JAMES MORRISON.

Exports of Butter.

Exports of butter this year have increased largely over those of last year. The total exports of butter to Europe from May first to August fifth, this year, have been 44,320 packages as against 26,341 packages for the same time last year. This increase is said to be due to the fact that there has been a material falling off in European markets of supplies from Denmark and other North European states. The dry weather that has prevailed in Europe, has caused a shortage of supplies, especially of the better grades. Over three-quarters of recent export purchases have been of creamery butter. It is believed that the export demand will continue strong enough to get rid of surplus butter and keep the home market in good condltion. Canadian producers have shared in this export movement to even a greater extent than Americans. Since May first the shipments were 163,381 packages as against 59,683 during the same pe iod of last year.

The World Cannot Show Its Equal

In STYLE, CONVENIENCE and DURABILITY.

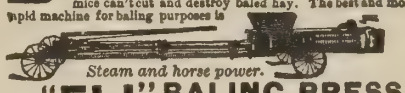
Body hangs but 17 inches from ground, and turns can be made in its own length. Sold direct to Dairyman at bed rock prices. For description and price address,

THE NATIONAL WAGON CO.,
Chillicothe, Ohio.

There's No Waste

either in knocked off ears or from sour, musty and mouldy corn fodder when using this

SCIENTIFIC CORN..... HARVESTER



Cuts corn at any height either in hills or drills. Being strong and well made of good material it will last. Every farmer can afford one. Send for catalogue, I.

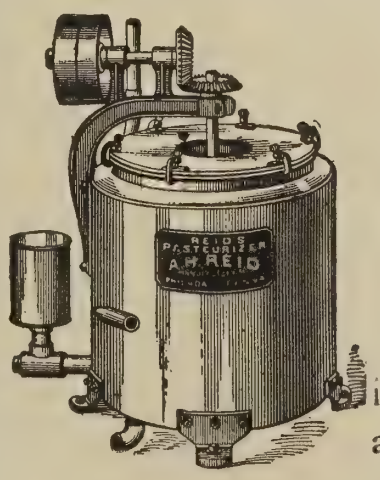
BALE YOUR HAY

It will keep better, sell better and save room. Rats and mice can't eat and destroy baled hay. The best and most rapid machine for baling purposes is



Steam and horse power.

The **"ELI" BALING PRESS.** Made in 38 styles and sizes to suit every case. All steel, light, strong, lasting. Write for free illustrated catalogue.

COLLINS PLOW CO., 1155 Hampshire St., QUINCY, ILL.

That Grass or Garlic Taste

as well as all other tastes and odors are removed by the Reid Pasteurizer. The cream and butter always retain their fine flavor, keep sweet longer and sell at better prices than unpasteurized The

REID Pasteurizer

is the only practical, scientifically constructed, and economically operated pasteurizer built.

Mechanicsburg, Pa., Aug. 1, 1899.

We have used Reid Pasteurizers in each of our four Creameries for twelve months, and now cannot speak too highly of them. Is this sufficient recommendation? We would not be without them under any circumstances.

Yours truly,
THE CUMBERLAND VALLEY CREAMERY CO.

Write for book about the best skimming machine made—the **Reid Long Spindle Separator** or for our new catalogue containing everything used in butter making.

A. H. REID, 30th and Market Streets, PHILADELPHIA, and CEDAR RAPIDS, IOWA.

Winter Dairying.

Mr. John Benson, Buxton, Derbyshire, read the following paper on Winter Dairying, at the Irish Conference of the British Dairy Farmers' Association:

There are various opinions as to the best and most profitable way of feeding dairy cows in winter, as also on the treatment of milk intended for butter and cheese making. I do not propose, however, to consider the different systems of feeding or dairying, but rather to give a *resume* of the results of my experience in the management of a herd of dairy cows and feeding experiments conducted at the Midland Dairy Institute during the last four years.

These experiments were undertaken to ascertain which foods produced the best quality of butter, and other experiments were also carried out in the dairy on the treatment of milk intended for butter and cheese making, with the object of producing a good flavored butter or cheese, resembling, as far as possible, an article turned out during the best season of the year.

The crops grown on the farm, and used for feeding the cows were: hay, oats, straw, mangles, cabbages, and occasionally swedes. In all the experiments oat straw and hay formed—as, of course one or the other will always do—a major portion of the ration, and the experiments dealt chiefly with the effects of cabbage and root crops, and also of various artificial foods, meal and grain, on the production of milk and the quality of butter and cheese made therefrom.

In all these experiments, the hay was fed long, the straw chaffed and partially steamed, and the pulped roots and meal mixed with the chaff before being fed. The cakes were given as a separate meal.

The chaffing and partial cooking of the straw was found to have a decided advantage over the unsteamed straw, but too much steaming and cooking was found to do harm to the health of the cattle. During one winter the chaff was cooked thoroughly, till in fact it turned brown. The cows, however, were not so healthy. They seemed delicate and took cold quickly, and were difficult to keep in good condition, and the calves from these cows in spring were delicate and difficult to rear. The cows also seemed more liable to abortion. At the same time, the milk yield was very good, and, no doubt, thorough cooking of food would be an advantage where quantity of milk is the main object, and where the cows are sold off as they become dry, and replaced from time to time by others in full milk. Ours, however, was a breeding herd, the best young stock being reared for the dairy, and the cows only sold when they proved barren or otherwise unfitted for the dairy.

Of the roots and green food given to the cows, we found that swedes produced or tended to produce, a good supply of rich milk and butter of excellent quality; and, provided the milk was handled properly in the dairy, there was no taint of turnips in the produce, whether butter or cheese, and the butter made during the periods when swedes were fed in abundance was good flavored, of firm texture, and a nice color.

Cabbages we found not to produce a good butter. It was naturally pale, wanting in flavor and body, and the milk fed largely on this food was particularly liable to be tainted, and, as a rule, was poor in quality. The quantity yielded was very good, and there is no doubt that the cabbages form a valuable food when the production of milk for sale in towns is the main object. The taints in the milk were found to decrease considerably when this green food was given out in the grass fields, which fact points to external contamination of the milk.

Mangels, though undoubtedly an excellent food, and far superior to cabbage, do not produce a particularly good flavored butter—certainly not so good as that from swedes. The butter is extremely pale, requiring a large use of artificial coloring matter. The milk, however, is not so liable to be tainted as is the case where cabbages are fed in abundance.

Of the artificial food stuffs and meals there is nothing, in my opinion, so good as a linseed cake, poor in oil, and maize meal. Maize meal, when fed in conjunction with straw chaff, pulped roots, hay, and a little linseed cake, low in oil, was found to produce a quality of butter, leaving nothing to be desired. On the other hand, linseed cake, very rich in oil, undoubtedly tends to the production of an insipid and soft quality of butter, and when this rich cake was fed at the rate of four or five pounds daily, the butter produced was not equal in value, by two pence per pound, to that obtained when the cows were fed on a poorer linseed cake and maize, as in the above ration. Of course, as is well known, a rich linseed cake will improve the condition of the cow, but what we want is a good quality of fat in the milk, and not on the cow's back. Cotton cakes, whether decorticated or undecorticated, I consider are foods more suitable for summer than winter use. The quality of the butter from these foods is fair, but too firm and brittle. Its effects on cows giving milk and on their progeny, when fed in large quantities in winter, is disastrous. It is all very well to say that analysis points it out to be a food quite as valuable as linseed cake, but we require palatability and safety in food stuffs besides mere quality. Bean meal, when fed in moderation, and oats, are, no doubt, splendid foods for butter and cheese production, but we found, as a rule, that when a fair price was obtainable, it was better to sell these food stuffs and replace with maize and linseed cake. At present prices, and taking weight and feeding value into consideration, better value can be obtained by selling oats and beans, and replacing with maize and linseed cakes.

Where butter and cheese production are the main objects in a dairy, wet brewers' grains should be avoided. Brewers' grains in the wet state are most detrimental to the quality of manufactured dairy products, and in making contracts for milk it has been my practice to stipulate that these be not used under any condition whatever. No doubt for the production of a large quantity of milk they are valuable and extensively used, but when such milk has to be worked up into butter and cheese the results are most unsatisfactory. Wet brewers' grains when fed in even moderate quantities produce a milk which is unstable and acidifies quickly. The return both as to quality and yield of butter and cheese is most disappointing. Dried grains, however, are no doubt a good deal superior to the wet grains, and are valuable for mixing with chaff, as they improve the appetite of cows and act medicinally. When fed alone, however, I find that many cows will not touch them, and even those cows which take to them well at first will refuse to eat them if the feeding is continued for a lengthened period.

There are other cakes, meals, etc., which are used to a certain extent by dairy farmers, but as I have dealt with the foods principally in use and have not had much experience of the others I shall proceed to remark upon the treatment of milk in the dairy.

In milk a few hours old many different types of bacteria may be found. Some may be favorable to the quality of the butter and cheese produced, while a large number act deleteriously towards these products. During the winter months these latter classes of bacteria abound, and, especially from November to February, we have a condition of things which is not at all favorable to the manufacture of the best quality of butter and cheese. The cows are, as a rule, kept in close sheds, and external contamination results. How to overcome these difficulties is a matter of importance to the dairyman. The lactic acid bacteria, which are, no doubt, essential to a good flavor, seem to develop very slowly during the winter months, allowing undesirable bacteria to gain the ascendancy. We constantly find in dairies where milk and cream are untreated during winter that bad flavors and undesirable qualities in the produce abound, which lessens greatly the market value of these products. The object of the dairyman, therefore, should be to so treat his milk or cream as to make it a suitable medium for the growth of desirable bacteria. Of course, as I have mentioned before, the food of the cow will exert a great influence on quality and flavor, but if milk is carelessly handled, no matter how good it may have been when first drawn, the butter, etc., obtained will be of low grade and the market value decreased.

When butter is made on the farm, the milk should be separated as quickly as possible, and while still retaining its animal heat. I am aware, however, that this is often impossible with evening's milk, which, as a rule, is kept till morning, re-heated and separated along with the morning's milk. The correct treatment of the evening's milk, therefore, deserves attention. It is essential that where milk is kept overnight, it should at once be passed over a refrigerator or otherwise quickly cooled. Nothing tends so much to produce undesirable flavor in milk as a slow or retarded cooling. I have invariably found that in farms where the evening's milk has been poured into the churns or receivers and allowed to cool gradually during the night, the flavor of butter made from such untreated milk was vile, and a great amount of after treatment was required to make butter from it which would be at all passable.

I do not consider pasteurization necessary when butter is made on the farm premises, provided attention is given the evening's milk as before described. I should, however, recommend that the cream be cooled to 70° or 75° F. immediately after separation, and a starter used to ripen the cream. This starter may be a preparation made from a pure culture, such as Hansen's, or, preferably, a quantity of clear sour buttermilk kept from a previous day's churning, and added at the rate of about two per cent, may be used. Where churning takes place only once or twice each week I find it best to add a smaller amount of starter to the first lot of cream put into the cream vessel, and as each lot is added to stir the bulk carefully. Often, however, a good flavor is not obtainable on a particular farm. The necessary bacteria may be absent. Under these conditions I have found it best to procure a little sour cream or buttermilk from a dairy noted for the quality of its butter. To get the best results it is necessary to at first take a quantity of separated milk and heat this to 150° F., cool down quickly to 90° F., and then add the sour cream or buttermilk. The mixture is allowed to cool slowly, and acidification should take place at a comparatively low temperature, or the resulting starter will be gritty and coarse. It is necessary to strain this starter before adding to cream.

It will easily be seen that by working on this method the desirable ferments will be introduced into cream, and that afterwards a correct flavor can be retained by using the sour buttermilk for future churnings, or a preparation can be made from day to day by inoculating pasteurized milk from the original starter.—*Agricultural Gazette*, Ireland.

The Hog Packers Want.

No animal has done more to lift mortgages and convert cheap farm products into ready money than the hog. He will grow and give a pretty good account of himself, even if treated upon the "root hog or die" plan, and yet no animal responds more quickly to careful, intelligent and common sense treatment. Through over refinement in breeding, or injudicious use of too concentrated or improper food, he sometimes comes to grief and rushes pell-mell over the cliff into the sea of hog cholera, as it were, as if he was really possessed with evil spirits, but with whatever shortcomings he may have, he is truly one of the best and most available money makers for the average farmer. For that reason a careful study of the hog and his treatment is well worth while. Mr. Louis Smith writes: The plan of the editor of the *National Rural* and *Family Magazine* to bring this matter to the attention of farmers is commendable, and I am glad to answer as best I may his practical questions as to the best and most profitable conditions for marketing this valuable food animal. In answering the question: "What weight of hog usually commands the highest prices, and why?" I should say from 175 to 250 pounds. Such hogs yield a larger percentage of high priced meat—they are not too fat. In a general way this answer will also apply equally well to the question: "What weight of hog is in greatest demand by packers, and why?" Although there are times when special cuts are wanted, or for instance, when lard is scarce and high, that heavier and fatter hogs will command a premium. Then again, there is always a demand for 170 to 190 pound hogs, suitable for making the best bacon. Such hogs sell at top prices even when the general average weights are running heavy.

A most affirmative yes can be given to the question: "In buying hogs, do you inquire how they have been fed, or upon what kind of food; and does the kind of food upon which they have been fatted affect the price, other things being equal? Wheat or corn-fed hogs bring the best prices. Hogs fed on soft food are discriminated against, and those fed only upon nuts and mast are oily and undesirable. In replying to the question: "What breed of hogs do you prefer, if you have any preference, and why?" will state that Swift & Co. prefer Berkshires and Poland-Chinas because they yield the largest percentage of high-priced products. On the other hand the Yorkshires and Tamworths are more favorably regarded in Canada and abroad, where the English bacon trade is catered to. The question: "Have you any preference as between the black and white hog? If so, why?" has an element of business sentiment back of it. Butchers who purchase whole carcasses prefer white hogs; they are more attractive for display. But for packing purposes no preference is shown. The black hog is as desirable as the white animal. The question: "Is there a sufficient demand for the bacon hog, such as is produced in Canada, Ireland or Denmark for the English market, to warrant an increase in the production of such hogs by the American farmers?" calls for a more extended answer. There is a sufficient demand for bacon hogs.

The English market each year uses a large and increasing amount of a superior quality of bacon. In the main it is supplied by home-curing and by importations from Ireland, Denmark and Canada. This bacon cannot be made from the ordinary American type of hog, nor can it be made from light hogs, young or otherwise, of the breeds we have in general use. Light hogs, of course, make light bacon, and there is occasionally a demand for light bacon that makes light hogs sell at a premium, but it must not be supposed that these light hogs are made into the class of bacon that the English market wants at fancy prices. If our farmers would produce a bacon-type of hog, using those breeds that furnish this product in Ireland, Denmark, or Canada, and what is still more important, feed and breed for bacon, they could produce it at a profit and still at a price which would enable American packers to supply the fine bacon to the English market. For such a type of hog the packer could and would pay a higher price

ATTENTION DAIRYMEN!

OVER EIGHT HUNDRED DOLLARS IS OFFERED IN PREMIUMS FOR DAIRY PRODUCTS AT THE

Wisconsin State Fair

MILWAUKEE, SEPT. 11, 12, 13, 14, 15.

REMEMBER all premiums are pro-rated, so each exhibit of any merit is sure to get its share of the money.

Each exhibitor will receive a score card, showing the score, with all defects found written thereon, in a sealed envelope. All exhibitors should send 60 lbs. Creamery Butter, 8 lbs. Dairy, and 6 lbs. of Prints. Cheese should be, Cheddar, 1 box, 60 lbs; Twins, Flats, or Daisies, 1 box, two in a box; Young America, 1 cheese not less than 8 lbs.; Brick and Swiss Cheese, 60 lbs., just as prepared for market. **Butter and Cheese** will be kept in **glass refrigerator** and **re-shipped or sold** the next day after the Fair closes, according to direction received. Write name and address on **bottom** of each package, to save mistakes.

Make all entries with Secretary at Madison, Wis. **J. W. THOMAS, Supt.**

1c a Pound WILL BE ADDED TO THE **Value of Butter** by the use of our Cultures at this season.

O. DOUGLASS BUTTER CULTURE CO., 81 Austin Street, CHARLESTOWN, MASS.

Well Drillers! Use LOOMIS' "Clipper" Driller.

The Standard of America!

Strongest! Takes least power! Carries heaviest tools! Drills much faster! Most convenient to handle! Will last longer and make the owner more money than any other Well Drill on earth.

We also make many other machines for drilling wells of all diameters and depths. Machines for Horse, Steam, and Gasoline Power. **Write for full particulars.**

than for the ordinary hog. A good deal of misapprehension on this point exists because light hogs do not always command a premium. As before shown, the fact that a hog is light is not evidence that he will make the high-grade bacon wanted. In fact, light hogs such as we get now, are used simply to make light bacon for ordinary use, and such bacon does not always command any premium over the heavier sorts. When it does the the packers pay more for this class of hogs; when it does not they pay less, because the balance of the hog is less profitable. Another point to be understood is that no packer can afford to undertake to supply any special grade of meat unless he is sure that he can secure a steady and sufficient supply of raw material. Unless there are enough bacon hogs to insure this sufficient supply it is not reasonable to expect them to command the price they would if the packer knew it was safe to notify his customers abroad that he would furnish them the bacon wanted in any quantity and for delivery at any forward time named. When asked whether "the bacon hog can be as profitably or more profitably produced by farmers in the corn belt than the common American hog?" I can only answer that this is a question depending altogether upon local conditions. The man who fattens his hogs as part of his cattle-feeding, using them to utilize the droppings, cannot grow a bacon-hog at all.

Whenever the daily receipts show a satisfactory percentage of true bacon hogs they will command a substantial premium. The question of whether that premium will be enough to offset increased cost of production will be settled by each individual for himself. We believe that the man who devotes his attention intelligently to the production of the bacon hog will get more money for his work than the ordinary hog raiser. The question of the corn belt cuts little figure, as an exclusive corn feed will not make the quality of meat wanted. Corn can be only one element in the food. The Canadians use largely peas, barley, oats, wheat bran and shorts. The need is for a food that will form a large percentage of lean meat, and corn furnishes fat and heat. The question, "From your experience as packers and marketers of pork, what suggestions have you to make to the hog raisers as to what is the most desirable hog for market and how should it be made?" is most important. I advise farmers to market younger hogs—hogs that mature at about six months of age, and weigh from 175 to 250 pounds. A painstaking, successful Iowa farmer, who aims to mature and market his hogs at six to seven months, weighing 220 to 230 pounds, says experience has taught him that with corn worth 25 cents per bushel, the first one hundred pounds of hog cost him $2, the second, $2.75, the third, $3.50, and the last hundred pounds of a 400-pound hog, $4.25. This in view of the fact that, as a rule, the 175 to 230-pound hogs are in best demand, and consequently sell at best prices, added to the tied-up capital and greater danger from disease, by holding hogs to make them heavier, makes a powerful argument for early maturity. If a feeder had unfinished cattle, and could not replace his 230-pound hogs with shoats, it might pay to hold longer; but circumstances always alter cases. As a rule, Americans seem to lack confidence in their ability to produce the best. It is not so with people in some other countries. In England nothing ever quite equals home productions. They pay more per pound for home grown beef than for American beef, but only when the latter is labeled. Sold strictly on its merit as beef, the American product always wins its way with the best judges, and I think it will be so with our hog products. If our farmers were in Canada, it would be wise for them to do as the Canadians do, and vice versa. We must work out our own problems in our own way. We believe that American farmers can make the most money, and produce the finest hogs in the world, by using, say, the bone and muscle-making grains upon grass until the pig weighs about seventy-five pounds, and then carefully bringing him to early maturity on good, sound Indian corn.—*Prairie Farmer.*

The Right Spirit.

Commenting on the conspiracy to override law which the oleo makers have engaged in everywhere, the Mankato, Minn., *Review*, says:

The State Dairy and Food Department does not let up a minute in its determined efforts for protection of the dairy interests and producers of food articles. The fourteen manufacturers of oleomargarine, backed by $46,000,000 of trust money, have doubled their product within the last year, tons on tons of which come into this state to rob the farmer and dairyman. The Department is relentlessly pursuing the adulterators of lard, with the determination, if possible, to drive every pound of the bogus stuff out of Minnesota. There is not a great corporation operating this stuff in the state but has been proceeded against. Oleo and bogus lard have got to go.

There is a vast difference in the quality of pork. Some is sweet, tender and juicy. Some is directly the reverse. Feed is largely responsible for this difference. In experiments, conducted for the purpose of determining the influence of food on the quality of pork, it has been found that milk, corn, barley, oats and peas produce the most solid and best flavored meat. Potatoes produce a soft pork. By-products of the flour mill make an inferior pork. Oil meals produce pork that is oily and of poor flavor. The meat made from feeding beans is without flavor, and hard and indigestible. Acorns do not make good pork.—*The Epitomist.*

CONCERNING OUR ADVERTISERS.

IN A NEW FIELD.

The Sharples Company, manufacturers and dealers in Cream Separators and all kinds of Creamery Machinery, is now located at Nos. 28, 30 and 32 South Canal Street, Chicago, Ill.

Realizing the advantages of a central location near to and in direct communication with all the dairying regions of the Ohio, Mississippi and Missouri valleys, the Sharples Company has established a western office, salesroom and warehouse at the above location.

The office is commodious and suitably appointed for the use of the manager and his assistants. The salesroom is well adapted to the exhibition of all kinds of machinery and fixtures used in dairies, creameries and factories. The store room furnishes ample storage for a large stock of separators, churns and creamery machinery. In the rear is established a machine shop for refitting and repairing dairy and creamery machinery and fixtures. The company is prepared to attend to the wants of their patrons, old and new, with their usual promptness and fidelity.

Mr. P. M. Sharples, the largest manufacturer of cream separators in the United States, is president of the Sharples company.

Mr. A. W. Rockwell, the secretary and treasurer, is favorably known throughout the dairying regions of the Northwest, having been for many years manager of the P. M. Sharples branch house in Omaha. Mr. Rockwell, as manager of the Sharples company, hopes to continue the pleasant business relation established with all his former patrons and also to make many new friends in this new and promising field.

It is the storm beaten fodder that is left uneaten, and it is the loss of this fodder that compels the farmer to feed his hay. The loss of corn fodder is a waste of a portion of the corn crop. As the fodder when properly preserved is nearly equal in value to the grain, no farmer can afford to allow his fodder to be wasted.—*Farm Notes in Philadelphia Record.*

Information of value, relative to the cutting, shredding and crushing of corn fodder, and the best means of feeding, is given in a pamphlet issued by Heebner & Sons, Lansdale, Pa., and will be sent free on application to all who read HOARD'S DAIRYMAN.

VETERINARY.

Queries in this department answered by WM. HORNE, M. D. V. S., Janesville, Wis.

COW PHYSIC—Three-fourths to 1¼ pounds Epsom Salts (according to age and size of animals) and two ounces of best ground ginger. Pour over this three pints of boiling water. When at 105° F., give gradually as one dose.

BRONCHITIS.—SORE EYES.

For three years I have had trouble with my calves. They come all right, and some of them do well all the way through, while some of them take a heavy hacking cough and rattle in the throat, while drinking and all through the day. They hold their heads low while coughing, and seem to have fever, as they can't stand sunshine at all. The disease is on the increase, as some of our cows have the same old heavy cough, but seem healthy otherwise.

I also have some cows and calves that have sore eyes (this too seems to be running through my herd); their eyelids swell up and look like what we call pink eye in horses; it usually lasts about ten days. L. W.

Ardmore, I. T.

ANSWER.

No. 1—Looks much like verminous bronchitis. This is also called hoose, husk and half a dozen local names. This disease is usually contracted by calves from two weeks to three months old which run in wet, damp pastures, or in a pasture where old cows graze. Separate the affected at once and keep in a dry, shady place. Feed of the best and most nutritious food, any of the oil cakes or oil meal, roots of any kind, carrots being the best. Put the calves into a closed room and burn and fumigate with flour of sulphur thrown upon a hot piece of iron, live coals of charcoal, for twenty minutes, not more, and see they are not too much affected. If they are, give them a little fresh air and stop fumigation. Give common table salt, one tablespoonful, or oil of turpentine, one tablespoonful, in milk, to be violently shaken before giving. Give each day, gentian, ginger and sulphate of iron, equal parts, half an ounce to three months' old calves. Less for younger ones, of course. Mix these thoroughly; each day for two to three days.

PERHAPS TUBERCULOSIS.

I have a cow that is stiff in her hind part and bunches are growing out on outside her hind legs below the stifle joint. She is getting very poor. Can it be from going into the water, as my pasture is along a river and the cows very frequently cross the river? The cow freshened about two months ago.

Camp Douglas, Wis. H. C. H.

ANSWER.

I don't like your symptoms at all. I am seriously in the belief you have a case of tuberculosis, and would advise you to get the state veterinarian to examine the cow. I would not use the milk. I don't think it is fit for use.

MANGE IN CATS.

Some time ago wrote the veterinarian this question: What can I do for my ailing cats? They have the mange. He read it cows and replied accordingly. Now, Mr. Doctor, this is a serious thing with us. Our cats are almost as necessary as the cows, but they keep dying or we have to kill them, get scabs, itch. Have tried a drug store preparation of vaseline, tar, sulphur and other things, but it is so hard to apply. Any suggestions you my offer will be very thankfully received.

Greenville, Pa. R. E. K.

ANSWER.

Dipping in a tan pit and then washing immediately in clean water, has cured many dogs of scabs, etc. Chloride of lime, one ounce, pure lard, or lard oil, 12 ounces, thoroughly mix and rub in all the scabs, every other day for three dressings, if needed.

RHEUMATISM.

My neighbor has three cows that have taken sick in the last two weeks. They get lame in the hind legs and their udders get caked and they dry up. The first one that got sick has lost the two hind teats, that is, they will give no milk; the second one is getting better and the last one is very bad; she chills bad and is not able to get up, and her water is just like blood. T. J.

Boaz, Wis.

ANSWER.

You tell what is wrong yourself. The cause in your case I know not. There are many causes for the conditions named. Almost anything that unbalances the general or local system is a cause. The teats are the effect of the disease; the symptoms point to several forms of disease; they will come O. K. when the cause is removed, no doubt. I believe rheumatism is the disease. Rub hard, three times the first day, and twice a day afterward, until the lameness is entirely gone, with oil of cedar, four ozs., four ffs. ammonia, two ozs., fish oil six ozs.; shake hard. Then find the cause and remove it. If you can, internally give two drams of prickly ash and half a dram of stramonium in two ozs. old whisky and four ozs. of water; on the fourth day give sharp dose of physic, then repeat the internal medicine for four days, and then physic dose No. 2. Keep dry, good exercise in the sun.

Horse Owners! Use GOMBAULT'S Caustic Balsam

A Safe Speedy and Positive Cure

The Safest, Best BLISTER ever used. Takes the place of all liniments for mild or severe action. Removes Bunches or Blemishes from Horses and Cattle. SUPERSEDES ALL CAUTERY OR FIRING. *Impossible to produce scar or blemish.*

PAGE WOVEN WIRE FENCE CO., ADRIAN, MICH.

A Year's Record With a Scrub Cow.

[*Press Bulletin.*]

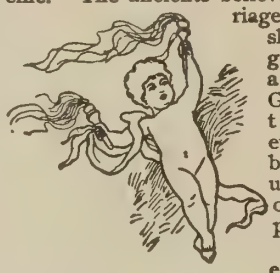
The best cow owned by the Kansas Agricultural College gave last year 9116 pounds of milk and 383.7 pounds of butter fat; value of products for the year was $73.17. For the best month last year she gave 977 pounds of milk and 37.12 pounds of butter fat. For the first month of this year her milk yield was 1250 pounds, which made 44.89 pounds of butter fat. This is an improvement over her best month last year of 273 pounds of milk and 7.77 pounds of butter fat, or 21%. Such gains show what can be done by feed and care, and if the farmers will pay more attention to this part of the work, they will realize more from their cows.

J. A. CONOVER,
Kansas Experiment Station.

What Does Milk Cost?

There is probably no farming question as to which there is so wide disagreement among farmers, as there is about the cost of milk.

It undoubtedly costs more in winter than it does in summer, and this was especially true under the old-time system of feeding on dry hay and cornstalks, with sometimes a little grain for variety, which, however, usually went to make fat on the body rather than to increase the milk flow. There was no inducement in those days to have cows calve in the fall, for the fresh flow came at a season when it was almost impossible to keep it up. Milk is always dearer in winter than in summer, but under these conditions the slightly increased price did not pay the extra cost, and all the winter-made milk had to be sold at a loss.



Now, however, a farmer who has a basement barn and silos to ensilage his corn fodder, can have cows drop their calves in the fall with some confidence that the winter product will pay its cost. Corn fodder is so much cheaper than is pasture on high priced land, that if it can be given in succulent form and if cows can be protected from winter's cold, the winter's milk does not cost any more than that made in summer, where the main dependence is on pasture. We believe that good pasture in June will bring more milk from a new milk cow than will any other feed. But that is not saying that even then it is the cheaper feed. It must be remembered also that June pasture fills out only a small part of the summer.

The grass is sappy and innutritious in May, and by July or August it either grows hard and woody or dries up so that cows will not eat so much of it, and what they do eat will not make so much milk. So great is the need of extra feed for cows at this time that corn drilled for fodder is often cut before it has even got into blossom, and when it, of course, has very little nutrition. So soon as corn matures sufficiently, it will furnish a ration that will materially increase the milk flow of cows at pasture. Indeed, many of the best farmers put their cows in darkened stables during August heats, partly to protect them from flies. They find that entire reliance on soiling with green corn or with clover makes a larger milk flow and makes it more cheaply than does reliance on pasture, even when corn is cut and fed daily as an adjunct to it.

This, we think, pretty nearly proves that, considering results, the winter feed of cows costs less than it does while they are at pasture. Most farmers deceive themselves into thinking that their summer pasture costs nothing, because they expend neither money nor labor to secure its product. The cow is turned in, eating with one mouth, but all the time trampling the tender grass with four feet, soiling the grass, besides more or less bruising it and injuring its roots. If the pasture is clover, this injury is so serious that stock ought never to be turned into a clover field until it is nearly ready to blossom. Until this time, clover is about the poorest feed that can be offered to a cow. But turn a cow into a field of clover when it is in blossom, and what will be the result? She will trample through it, biting off the clover heads and soiling or destroying fully twice as much as she eats. If the same clover is cut and fed green to the cow, she cannot separate the heads from the stem so well and will eat the whole of it. In this way three times as much feed will be got from an acre of clover as can be secured by pasturing. Some of the clover will be soiled so that the cow will not touch it through the remainder of the season.

Every farmer who has pastured clover knows that toward fall, while most of the clover will be eaten down almost to the roots, there will be a considerable portion that has grown hard and woody, so that it has little nutritive value. When the clover is eaten off early, the second growth promptly springs up and is both palatable and nutritious. That is what grows up after the first crop has been cut for soiling or for hay. A second, third and even fourth crop of clover may be grown if the soil is rich enough, and each one will be more nutritious than the first. This repeated cutting of clover is far better for the root growth than pasturing it can be, for in pasturing, the constant trampling of the ground hurts the plant and lessens both its roots and top growth. In short, clover will usually produce, not only three times as much feed when cut with a scythe or mower, as when pastured, but it is nearly or quite three times as much benefit to the land. When the clover is cut, more or less leaves fall upon the soil, and it is the rotting of these that doubles and trebles the growth that the clover would otherwise make. The cow returns only the excrement from the clover she eats, but that is not in condition to help the clover growth materially the same season.—*Boston Cultivator.*

In the mythology of Ancient Greece Hymen, the god of marriage, was the half brother of Esculapius, the god of medicine. The ancients believed that marriage and health should go together, and as a result the Greeks of that time have ever since been looked upon as types of physical perfection.

Sickly mothers cannot bear healthy children. The prospective mother should use every precaution to preserve and foster her health. Not alone for the sake of the little one to come but for her own sake. A perfectly healthy woman is in no danger and in very little pain at her time of trial.

There must be due preparation for this time. Nature makes the preparatory period three-fourths of a year and women who take the hint from nature and use the time properly need have no fears of the outcome. Dr. Pierce's Favorite Prescription is a medicine designed to cure all distinctly feminine ailments and taken during the period of gestation it renders childbirth easy, safe and comparatively painless.

It is the invention of Dr. R. V. Pierce, of Buffalo, N. Y., a regularly graduated physician and skilled specialist in the cure of all diseases of woman.

Mrs. Orrin Stiles, of Downing, Dunn Co., Wis., writes: "I cannot praise your 'Favorite Prescription' enough, for I have not been as well for five years as I now am. In July last I had a baby boy, weight 11 lbs. I was only sick a short time, and since I got up have not had one sick day."

Sick women can consult Dr. Pierce by letter free of charge. Every letter is held strictly private and sacredly confidential.

Designing *men* work on women's feelings, by advising women to "write to a woman who understands woman's needs." It is useless to seek advice about disease of any woman who is not a physician. So far as known no qualified woman physician is connected with any proprietary medicine establishment.

THE JONES UMBRELLA "ROOF."

A NEW UNION TWILLED SILK "ROOF" $1.00

RE-COVER YOUR OWN UMBRELLA.

The Adjustable "Roof" fits any frame, requires no sewing, and can be put on in a minute. You can re-cover your own umbrella without the slightest trouble or moments delay.

Take the measure (to the fraction of an inch) of your old umbrella; count the number of outside ribs; state if the center rod is steel or wood; send to us with $1.00 and we will mail postpaid, a Union Twilled Silk 25 or 26 inch Adjustable "Roof" (27 or 28 inch, $1.25; 29 or 30 inch, $1.50). Umbrella "Roofs" all sizes and prices from 50 cents to $8.00 each, according to quality. If you are not absolutely satisfied in every particular, send the "roof" back, and we will refund the money *at once*, including stamps you have used for postage. Over a quarter of a million "Roofs" sold.

Booklet, "Umbrella Economy" with simple instructions necessary with your order.

All first-class dealers sell Jones Umbrella "Roofs."

The Jones-Mullen Co., 396-398 Broadway, New York.

Manufacturers of the highest grades of Umbrellas to the largest stores in the world.

Purity and Dryness

ARE QUALITIES THAT DISTINGUISH

Diamond Crystal Salt.

The relative purity of the dairy salts of the world is given in a valuable bulletin lately issued by the UNIVERSITY OF WISCONSIN.

Speaking of DIAMOND CRYSTAL, Prof. F. W. WOLL says:—

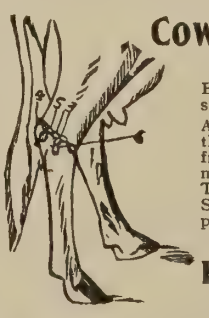
"The claims of this company for exceptional purity and dryness in their salt are fully substantiated by the analytical results obtained by the writer."

Lime and chloride impurities injure butter; damp, heavy salt is unfit for dairy use. **"The Salt that's All Salt"** is both PURE and DRY. Every dairyman should insist on having it.

DIAMOND CRYSTAL SALT CO., St. Clair, Mich.

DAIRY AND STOCK FARMERS Will do well to inquire about the fine meadows in Aitkin county, Minnesota, where splendid stock lands can be bought for $3.00 to $5.00 per acre on 10 years time at 6 per cent interest. Cheap railroad rates whether you buy or not. For maps, rates and further particulars write L. B. ARNOLD, Agent, 901-5 Guaranty Building, Minneapolis, Minn.

ILLUSTRATION.



In buying machinery of any kind the buyer makes a radical mistake if he does not insist upon getting that machine which has the most points in its favor, one that is thoroughly adapted to the work it is intended to do. The capacity, the strength, the durability, are all points which must be taken into consideration, as well as the simplicity of operation and the cost.

We show on this page an illustration of the Eli Continuous Travel Press in operation, and can highly recommend it to hay growers and shippers. It possess in the first place large capacity so that

it is economical in operation, and in the second place, sufficient strength to make heavy, compact and closely compressed bales when a large quantity of hay or other material is fed into it. It turns out a solid uniform bale, in striking contrast with the loose and bulky bales so often seen upon the market. Some idea of the power of the Eli may be gained from the fact that a 500 pound pull of the team applies more than 30,000 pounds pressure on the charge. Of course, to withstand this pressure the press must be very solidly built and the manufacturers have seemingly succeeded in building some of the strength of Gibralter into the Eli. Every care is taken in the construction of the Eli and every press is backed by the maker's reputation. The press can be telescoped so as to require but little room in hauling or storing.

In addition to the horse power press the Collins Plow Co. also makes a full line of steam power presses with every improvment that mechanical genius can devise to facilitate their work. They will send catalogue upon application.

Cow Hopple

For Kicking Cows.

Either from habit or from sore teats. **Price 50c.**

Also have a **Wart Cure** that will remove warts from horses, cows' teats or man. **Price 25 and 50c.** The goods are warranted. Sent Postage Paid. Send postal card for circulars.

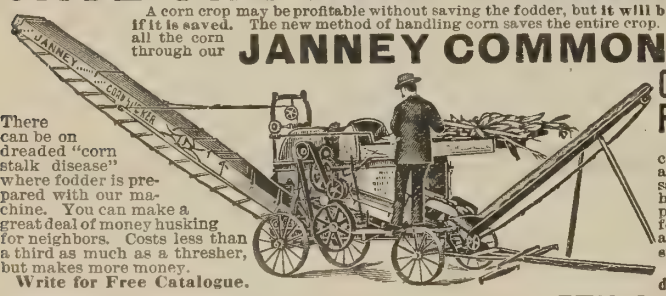
SMALLEY MFG. COMPANY, Sole Makers, MANITOWOC, WIS.

MAKE ONLY SWEET ENSILAGE

Ever since the ensilage system has been introduced in this country it has been the ambition and effort of siloists to ***produce sweet ensilage.*** The making of sweet ensilage depends principally upon two things—***1st.*** the use of a well matured crop and ***2nd.*** upon low fermentation. Granting the maturity of the crop, shredded ensilage makes the sweetest ensilage. The reasons are, that shredded material is of a nature that makes it pack much more closely in the silo. That means exclusion of air; there can be no extreme fermentation and consequent development of acid without the free action of the air. ***Shredded ensilage possesses other advantages in addition to its sweetness:—*** it is eaten with great avidity by animals, being a long, soft substance and free from any sharp angles and corners to cut or lacerate the mouth and gums; it is therefore fed with less waste.

The best way to Shred Ensilage is with the

St. Albans Ensilage and Fodder Shredder.



It is the Original Shredding Machine and all other so-called shredders are merely imitations of this one. ***It will certainly pay you*** to look into the merits of this proposition and machine before buying. We mail free a pamphlet on the subject.

ST. ALBANS FOUNDRY CO., ST. ALBANS, VT.

SAVE THE WHOLE CORN CROP

A corn crop may be profitable without saving the fodder, but **it will be twice as profitable if it is saved.** The new method of handling corn saves the entire crop. The new way is to run all the corn through our

JANNEY COMMON SENSE Corn Husker and Fodder Shredder

There can be no dreaded "corn stalk disease" where fodder is prepared with our machine. You can make a great deal of money husking for neighbors. Costs less than a third as much as a thresher, but makes more money.

It husks out all of the corn clean, and shreds all the fodder at the same time. Makes clean, healthful food, as the patented screen in the feed elevator takes out all the **dust, dirt, smut,** etc.

Feeds and Feeding

By Prof. W. A. HENRY,

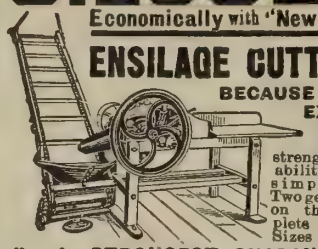
Wisconsin Experiment Station.

This book should be in the hands of every stock feeder in the country. Every reader of HOARD'S DAIRYMAN ought to have it. It is a large, well bound book, nicely printed, over six hundred and fifty pages. Price $2.00

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Four Yearly Subscribers at $1.00 Each ($4) Will Secure It as a Premium.

Of This Book Hon. JAMES WILSON, Secretary of Agriculture, Washington, writes as follows:



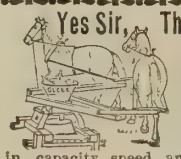
"Prof. W. A. Henry, Dean of the Agricultural Department of the University of Wisconsin, has recently given to the American student and the American farmer a work on feeds and feeding. Singularly enough, up to this time we have had nothing along this line sufficiently comprehensive from both the scientific and practical standpoints. We have had very able works from both, but Prof. Henry is the first to combine science with practice, and give us a work that will be of value alike to the instructor in the Agricultural College, to the student who is seeking the principles underlying feeding, and to the practical farmer who feeds.

This publication will take its place immediately in the college library, and ultimately in the private library of every farmer in the land. When the instructor, student or practical farmer inquires where there is a work thoroughly exhaustive of this subject, he can now be referred to Prof. Henry's book.

Sent as above, or will be forwarded, carriage paid, on receipt of price, $2.00.

SILOS Are Filled Quickly and Economically with "New Hero"

ENSILAGE CUTTERS



BECAUSE THEY EXCELL in rapid work, strength, durability and simplicity. Two gears only on the complete cutter. Sizes to suit all needs. **STRONGEST GUARANTEED.**

SOMETHING NEW: OUR UNIVERSAL SWIVEL CARRIER, runs at any desired angle, and can be changed from one angle to another without stopping cutter. New 160 page catalogue mailed **FREE.** Tells all about Hero Ensilage and Fodder Cutters, Corn Huskers Sweep and Tread Powers, Feed Mills, Goodhue, Wind Mills, Shellers, Peck's Corn Thresher, etc.

APPLETON MFG. CO. 65 FARGO ST., Batavia, Ills.

EVERY MONTH A PAYING MONTH.

Nine out of ten creamerymen cannot say this of their business; there are always some months in the year when their business does not pay, and it is these dull months which make the creameryman grow gray headed.

There is a way to make every month a paying month, have you ever thought what it is? What is it that makes a dull month in the creamery business? Shortage of milk, is it not? The manufacturing expense is nearly as great in making five tubs of butter as in making ten, but the profit on the latter is twice as much.

A number of creamerymen have hit upon a plan which insures a good supply of cream every day, and while some days are better than others, the results are such that every month returns a nice profit to the creameryman's pocket. The plan is this: Place Farm Separators with patrons too far distant to make the hauling of milk practicable and with others who will not send their milk to the factory because they havn't a large amount, but who would send their cream if some one would call for it.

This is no theory, as the plan is proving a success wherever tried and every creameryman who will test it can increase his profits from three to five dollars a day under the most ordinary conditions. Three dollars a day means over a thousand dollars difference in a year's business and there are not many who would knowingly let a thousand dollars slip through their fingers.

We will explain the plan more fully to any creameryman who will write us. We know it will pay you to investigate. It requires no additional capital; we will look after that, and all you need furnish is the necessary "push" in placing machines.

This is no "friendship" affair, it's just a question of whether you want to make money or not. We leave it with you to answer.

A Life Insurance Policy

is a most excellent thing in any occupation, but it seems a little hard that it should be enforced upon butter makers who are operating a certain kind of separator. Still it is the only way in which he may protect his family, having thus taken his life in his hands. These "complicated separators" have earned the label "Dangerous" by their long list of dead. It was a complicated separator that burst and so seriously injured buttermaker J. W. Segar, at Pecatonica, Ill., on April 12th. It was a "complicated separator" that burst and killed Albino Balzari, at Oso Flaco, Calif., on April 20th. Is there no remedy but an insurance policy? Oh, yes:

THE SHARPLES TUBULAR SEPARATOR

is a sure and effective remedy. These and all other Sharples made separators are absolutely safe. Among the multiplied thousands of Sharples made separators in use in this and other countries, not one has ever burst or otherwise injured anybody. If you value your life or that of your employees, Sharples Separators are the ones to buy. They will do all things which any separator will do and do it better and cheaper, and then they are absolutely "burst proof." The SHARPLES TUBULAR SEPARATORS replace many of these "complicated separators." THE DIAMOND CREAMERY CO., largest manufacturers of butter in America, use the TUBULAR and have thrown out the Alpha. "HORTONS" of New York, largest manufacturers of ice-cream in America, use the Tubulars and have thrown out the Alphas. "DARLINGTONS," the highest priced butter men in America, use the Tubular and have thrown out the Alpha. Scores more have done the same and thousands more will do it.

EXPERT TESTIMONY

SUBJECT:

Disbrow Combined Churn and Butter Worker

Witness: A. M. LARSON, Meriden, Kan.

MERIDEN, Kan., August 6, 1899.

T. J. HOWE, Esq., Owatonna, Minn.

Dear Sir:—Yours of the 1st inst. to hand, and in reply will say, that I have used a Disbrow No. 6 for about a year and a half, and it has worked to my entire satisfaction. The churn is very light running and the engineer says, "it takes only about one-half the power it did to run the 400 gallon box churn which we had in before we got the Disbrow." While we had the box churn we could hardly churn while the separators were running, as it would shake them and make them tremble so it was hardly safe to be in the room where they were. We experienced nothing of that kind since we got the Disbrow; it runs steady and causes no vibration, the gearing is very simple and is changed from churn to worker and reverse.

I have less trouble with mottles since I have used the "Disbrow." When the butter is taken out of a box churn to be worked, the temperature, either warm or cool, the surface of the butter, as it is hard in an average creamery to have the temperature the same as the butter, the soft part gets worked or overworked before the hard butter gets worked, and the result is badly mottled butter. The combined churn and worker keeps the butter at an even temperature, and consequently less mottles.

I always revolve the churn twice, in slow gear, after I have salted the butter and before I change it to a worker. To revolve the churn in fast gear is very hard on the churn and should never be done at the above stated time, but when put in slow gear the churn revolves as smooth as if there was no butter in it, and the revolving of the churn two to three times after salt is added before changed to worker, incorporates the salt with the butter.

I have churned 1,000 pounds at one time in the No. 6, but think it a little too much; 900 pounds is about right. I do not think it is worth the while touching upon the work that is saved by using the combined churn and worker, as I think it saves the buttermaker half the labor there is in using a box churn.

Trusting that my information is what you want, if there should be anything I have not touched upon, will be pleased to give you the information I can.

Respectfully yours.

A. M. LARSON, Buttermaker.

Star Milk Aerator AND COOLER.

If you have milk worth cooling at all, it is certainly worth while to cool it thoroughly. An efficient Milk Cooler will cool to within two degrees of temperature of water used; the Star does this and also AERATES.

If you would like to know the reason why, send for 1899 Catalogue of Sanitary Dairy Apparatus.

To be had for the asking.

STAR MILK COOLER CO., Haddonfield, N. J.

DAIRY AND STOCK FARMERS Will do well to inquire about the fine meadows in Aitkin county, Minnesota, where splendid stock lands can be bought for $3.00 to $5 00 per acre on 10 years time at 6 per cent interest. Cheap railroad rates whether you buy or not. For maps, rates and further particulars write L. B. ARNOLD, Agent, 901-5 Guaranty Building, Minneapolis, Minn.

Dairymen, when Visiting the State Fairs,

BE SURE AND LOOK UP OUR EXHIBIT.

There you will find our representatives who will be pleased to show you

The Improved U. S. Separator

and explain its many points of excellence. Be sure and investigate its merits before purchasing any other make. It is fast being recognized as the best for every day use.

The U. S. the Queen of Separators.

MIDDLEBURGH, N. Y., August 10, 1899.

About a year ago I desired to purchase a separator, and naturally I examined very thoroughly the different ones advertised. Becoming convinced that the Improved U. S. was the best, I accordingly purchased one, and a full trial for over a year has proven the wisdom of my choice. It is the most perfect in construction, skims perfectly clean, runs so easily that a child can operate it, and, in fact, is the acme of perfection. It is the queen of separators, and it affords me great pleasure to forward this unsolicited testimonial.

J. E. YOUNG.

Reading notices, 50 cents per line (nonpariel measure) each insertion.

STATISTICS of the amount of oleomargarine sold in the United States during the year ending June 1, 1899, furnished the pure food department of Pennsylvania, show that during that time there were 87,800,000 pounds of oleomargarine sold in the United States. The farmers lost over $12,000,000 by it being substituted for the real article.

IT is stated by butter experts in Chicago that a very large per cent of the number one creamery, sold on South Water Street, is the farm dairy product mixed with spoilt butter. How long will it be before that Illinois Dairy and Food Commisioner gets to work? What between oleo, process butter and the blended article, some one is going to be very busy, if he does his duty as it should be done.

THE editors acknowledge with much satisfaction the receipt of cards announcing the marriage of Prof. John W. Decker, of the Wisconsin Dairy School, to Sarah Elizabeth Hurlbut, of Elkhorn, Wisconsin. We congratulate John most heartily and can assure the bride that thousands of her husband's friends among Wisconsin dairymen unite with us in best wishes for her future happiness.

IT is evident that the "Holland Process" butter is being made in large quantities and a corresponding number of dairymen are getting fooled out of their money to pay for the "butter rennet," and will be fooled still worse if they suppose that they can delude commission men, or other customers, into buying their hydraulic butter a second time.

The Minnesota Dairy commission has seized forty tubs of the stuff and the makers are consequently "out" the whole amount. Instead of selling water for butter as they expected to, they stand a very good chance of prosecution for adulteration of food.

As another illustration that it is the man and the cow, and not the location that determines success in dairying, we instance the case of Mr. Amos Vaughan, of Tillamook, Oregon. He has a dairy of twelve cows, and from April 10, 1898, to February 2, 1899, there was sold from this herd 3,124 pounds of butter.

Average per pound	$ 0.1987
Average per cow	51.7250
Amount of cash received for same	620.70
Eight head calves	60.00
Pork	62.50
Total	$743.20

THE Illinois Dairy Union has taken up the prosecution of dealers in oleo in Chicago, who sell it for butter, and have sent out notice to a large number that they propose to continue prosecutions until the fraudulent sale is abandoned.

A case was made against J. F. Somes, trading under the name of the Ohio Butter Co. This case was not contested and Mr. Somes paid the fine, $25 and costs. A large number of other dealers who have been selling butterine for butter are on the list for prosecution. The Union proposes to keep up this fight until the fraudulent sale is thoroughly eradicated in Chicago. This line of work will have the sympathy and support of not only the producers of pure butter, but the consumers as well, who desire to secure the pure article.

IT WOULD NOT SOUR.

J. J. Billingsly, President of the Indiana Dairymen's Association, is strongly opposed to the use of poisonous preservatives in milk. In a recent interview in the Indianapolis *Seutinel* he relates the following incident:

"Consumers generally have had no idea of the material effects of formaldehyde when used to preserve milk. As an instance I recall that not long ago a lady of my acquaintance went to a neighbor's house to borrow some soured milk. The lady of the house said that she had no soured milk but some sweet milk which she would place in a vessel beside a hot stove and that the would-be borrower might return in four hours, when the milk would be soured for her. She did not return for ten hours. The milk had been by the hot fire all the time but was still perfectly sweet. She went away and returned fourteen hours later. Meanwhile the milk had remained by the hot stove twenty-four hours, and was still sweet.

Property of J. R. BOWEN, Morley, Ill.

MINNESOTA'S CREAMERY INTERESTS.

The St. Paul *Pioneer Press* has taken a census of the creameries of Minnesota, and the amount of their annual product from which we glean the following interesting facts:

Total number of creameries	673
Number of creamery patrons	52,320
Capital invested	$2,700,000
Cows supplying milk	400,000
Milk received in 1898, pounds	1,382,718,000
Butter made in 1898, pounds	62,849,000
Butter shipped from state in 1898, pounds	50,000,000
Gross receipts in 1898	$10,370,000
Operating expenses in 1898	$1,094,500
Paid patrons in 1898	$8,546,400

Of the eighty-two counties in the state seventy possess creameries.

The capital invested is about $2,700,000. The 400,000 cows at $30 each, are worth $12,000,000. The value of 52,320 farms supporting the industry is put at $130,000,000. The total value of the investment in Minnesota is upwards of $160,000,000 when the value of the 100 cheese factories and the city milk supply dairies are included.

Over one-fourth the farmers of Minnesota are patrons of creameries. The average creamery gets milk from about six hundred cows. The average number of cows per patron is from seven to ten. The average milk yield per cow is 3,500 pounds and the average butter yield is 160 pounds.

The largest average milk yield is in Steele County, 4,660 lbs. per creamery cow, and the next highest average is in Freeborn, 4,450 lbs. Brown follows close after with 4,056 lbs. The average per cow for the seven counties, Meeker, Martin, Goodhue, Freeborn, Rice, Steele, Kandiyohi, is 3,700 pounds of milk a year. The average from 133 creameries out of a total of 329 in the twenty principal creamery counties is 3,600.

Freeborn leads with the highest average butter yield per cow, 211 pounds a year; Steele and Brown following with 206 and 189 respectively. Rice is not far behind with 171, and Blue Earth 169. The average for the twenty principal dairy counties is 167 pounds per cow. In some of the new dairy counties the average butter yield per cow drops as low as 100 pounds. The average is a scant 160. There is apparently great room at this point for improvement in the dairy type of the state. The fact that the average butter yield per cow in Freeborn is 75 to 100 per cent larger than in other counties that might be named, explains why Freeborn makes dairying pay while the other counties in question see little money in it.

The books of the creameries in twenty counties show that the average yield of butter is one pound to twenty-two pounds of milk. The average creamery patron sends about 26,400 pounds of milk, from which is made 1,200 pounds of butter. Not far from 80% of the butter goes to New York. The cost of transportation in refrigerator cars is one cent a pound. The receipts of Minnesota creameries in 1898 exceeded $10,370,000.

The 52,320 patrons of 673 Minnesota creameries took away over $8,500,000 as receipts for milk and cream, which was equivalent to 13.6 cents per pound of butter made from the milk they furnished, without any labor cost to them for making and shipping butter to market. It made their milk worth about 62 cents per hundred and made the milk of the 400,000 cows bring in a little over $21 per head.

THE FUTURE RESTS WITH THE COW.

Minnesota's success with the creamery has been absolute. The future development of Minnesota's dairy interests depends upon the breeding and feeding of the dairy cow. In this direction, Minnesota, as other states, has wide room for improvement.

It is significant that while the average butter product of the Minnesota creamery cow is only 160 pounds, Prof. Haecker, at the State Experiment Station, has no trouble in getting 300 pounds from the common cow by scientific feeding and care. In discussing this important theme, Prof. Haecker says:

"The increase in the cost of food to produce this gain of 140 pounds in the cow's yearly butter product is only $5. The gain in butter at 15 cents per pound for 140 pounds, is $21, and the additional skim milk is worth $4.50, a total increase of $25.50 in the value of the product for an outlay of $5 extra in food. This is a net profit of $20.50 per cow, which for the 490,000 cows furnishing milk to Minnesota creameries, aggregates $8,000,000 per annum as the result of scientific dairy feeding."

Prof. Haecker has demonstrated the practicability of his theories in yearly experiments extending over eight years at the state farm. His experiments have secured the attention of the national department at Washington, and all over the dairy districts of America. Nor has his work failed to have its influence in Minnesota. In Freeborn and Steele, where the greatest attention has been paid to his experiments by Minnesota dairymen, the butter product per cow has risen to 211 and 206 pounds respectively, which is about 30% higher than the average for the rest of the state, and double the average of a dozen or more of the poorer counties.

Suffocation in a Silo.

ED. HOARD'S DAIRYMAN:—There has just occurred in our state at Wausau, Wisconsin, an accident, the cause of which should be clearly understood, as it might be repeated whenever conditions are favorable.

Three of the inmates of the County Asylum went into the silo in the morning, for the purpose of spreading and tramping the silage, but were at once overcome by the carbonic acid gas which had been generated during the night, but which could not escape on account of the position of the lowest open door.

Mayor J. H. Reiser, trustee of the Marathon County Asylum, writes me: "Our silo is twenty-five feet inside diameter and twenty-eight feet to the top of the plates, with one 2′ 8″×5′ opening in the roof for the cutter elevator. We have three openings 3′×4′ 6″ on the side leading to the barn. The first opening is ten feet from the bottom, and the other openings about six feet apart. We had our silo filled above the second opening and about six feet below the upper door. We had been cutting six days in filling the silo, and the day before the accident occurred, had been filling all day. The opening in the ceiling had been left open all the time, and the doors in the sides had been left open until after we got up to them in filling."

With this statement of the conditions, the cause of the accident is clear.

1. When green material is cut fresh into a silo, carbonic acid gas is generated at once, and rapidly by the living cells until they die and it is this respiration of the living but mutilated plant cells, which is at once the source of the first heating of the silage, and of the carbonic acid gas given off.

2. When this silo was left at night with the silage six feet below the open door, the stillness of the night, the rapid generation of gas and its heavier weight than the air, caused it to accumulate to a depth of six feet in the silo.

3. When the men entered the silo they were at once submerged beneath the carbonic acid gas, in which they drowned as quickly as if they had been beneath water.
